On admission she was in a deep coma, very collapsed and failing to respond to any form of stimulus Stertorous respiration rate 25–30, pulse 120 temperature 99°F Skin dry and hot slightly cyanosed Mouth foul with dry sordes, Pupils contracted but reacting Deep reflexes suppressed Lungs clear B P 170 110 Retinal arteries constricted Other systems virtually healthy Freely incontinent Albumin in catheter specimen of urine

Until we were able to obtain the picrotoxin some three hours later the routine treatment for hypnotic poisoning was initiated This consisted of gastric lavage lumbar puncture, intravenous saline and intranasal oxygen However no significant change was observed in the patient's condition and she was still in deep flaccid coma when the treatment by picrotoxin was started This was given by intravenous injection in divided doses of 2·0 c cm of 0·4 per cent solution (1·0 c cm of which contains 3 mg) As can be seen from the following table the 'awaken' effect was rapid In less than three hours she

recovered sufficiently to ask for a drink of water and to hold the glass herself while she drank a tumblerful.

Date in May	Time	Picrotoxin (mg.)	Clinical condition
6	9 P.M.	—	Admitted to hospital. Deep coma (duration possibly 24 hours)
	12 MDN.	6	Respiration quickened and deepened after 2 minutes. Pulse slowed from 140 to 115, becoming fuller. B.P. unaltered
7	12 15 A.M.	—	Began grimacing. Becoming restless
	12 45 A.M.	6	Purposive movements of mouth, frontalis and orbicularis. Pulse 120
	12 50 A.M.	6	Stertor gone. Eyeballs rotating. Movement of mouth and lower jaw
	12 55 A.M.	6	Alæ nasi working. Still unable to respond to commands
	1 20 A.M.	6	Resentful of injection. Considerable movement of free arm. Beginning to cry intelligibly "I want to get up." Grip reflex present
	1 50 A.M.	6	Animated movements, followed by relapse into more restful coma as though tired. Jaw dropped. Pulse 110
	2 10 A.M.	6	No change. Still as though sleeping
	2 45 A.M.	—	After being pinched she stirred and asked for drink of water. Took glass, held it herself and sat up while she drank 10 oz.
	8 A.M.	—	Comatose again. Not easily stimulated to movement
	12 5 P.M.	6	Still lethargic
	12 25 P.M.	6	Restless
	12 45 P.M.	6	Became very restless after this. Muttering and sobbing. Speech not yet clear
	1 P.M.	—	Still lying with closed eyes but in answer to commands able to open them and protrude tongue. Taking drinks. T. 99·4° F., P. 115, R. 26
8	Throughout day	—	Rather drowsy but revived at times. Fairly restless. Somewhat tearful. Able to take solid food and drinking well. (Intravenous saline discontinued.)
9	et seq.	—	Completely resuscitated. Cheerful. T. and P. normal. B.P. 125/75
16	—	—	Discharged home. No sequelæ when last heard of two months later

DISCUSSION

It will be noticed that the picrotoxin was at first given intermittently for two hours until the patient had been fully stimulated into effectual restlessness. For the next ten hours it was discontinued until a gradual relapse required a further 18 mg. In the intervening hours and subsequently, until 10 P.M. two days later, 4 c.cm. of Coramine was injected intravenously at two-hourly intervals. A total of 54 mg. of picrotoxin and 112 c.cm. of coramine were given. It must, however, be emphasised that the effect of the picrotoxin after every injection was dramatic and obvious whereas no remarkable result was evidenced at any time from the coramine. Further, coramine was entirely withheld until the patient had been revived initially by the first 36 mg. of picrotoxin. It was then given for economic reasons in an attempt to sustain the favourable effect of the picrotoxin. It was quite clear to us that the observed effect of picrotoxin in this case could not possibly be confounded with that of the other remedies used.

After each injection of picrotoxin a latent period of one to three minutes preceded the signs of response. The reactive irritability would reach its peak after several minutes then to subside if no injection immediately followed, leaving the patient again in coma. The effect of this temporary stimulation was each time to lighten the degree of coma into which she would afterwards lapse, so that narcosis became successively shallower. It is possible that we could have prevented these relapses by administering picrotoxin more frequently or in bigger doses. Nevertheless we felt that so long as we were able to keep our patient restless, thereby increasing her pulmonary ventilation, we could considerably reduce the danger of the most serious complication of barbiturate poisoning, namely, pneumonia. This, indeed, we effected and in the majority of the recorded cases pulmonary complications have been similarly avoided.

The problem of dosage remains controversial (Rovenstine 1938) but it would seem that far larger therapeutic doses are both possible and safe. The dangers of overdosage of picrotoxin in barbiturate poisoning have conceivably been exaggerated but it may be borne in mind that over-stimulation can produce convulsions which in turn are followed by increased depression. We gained the impression from this case that had it been more severe we could with impunity have given larger doses of the drug. Previous reports have shown that heroic therapeutic doses can be tolerated which are many times greater than the lethal dose of picrotoxin. It is, therefore, of vital importance only to employ this potent antidote in cases where the diagnosis of barbiturate poisoning is certain. Intravenous picrotoxin should be given continuously until spontaneous movements, restlessness and a substantial decrease in the coma are apparent. After this intramuscular injections may be sufficient to sustain the stimulatory effect (Kohn 1938). As a precautionary measure Evipan or Pentothal should be kept ready as a rapid antidote to an overdose of picrotoxin. Bleckwenn and Masten have advocated a dosage at the rate of 1 mg. per minute and Murphy et al. (1937) have suggested an initial 5 mg. which can be doubled after twenty minutes, continuing with smaller doses of 2–5 mg. until the patient emerges from coma. The largest dose recorded without ill effect was 2134 mg. in a single case (Rovenstine). We venture to predict that in the future the specific value and comparative safety of picrotoxin in preventing death from barbiturate poisoning will be abundantly confirmed with the experience of further clinical trials.

CONCLUSION

Picrotoxin, a violent convulsant poison, can be used with safety in relatively large doses in barbiturate poisoning wherein it has proved to be dramatically effective in saving life.

A congress on Nutrition and Education will be held at British Medical Association rooms, Edinburgh, on Saturday, Oct. 14, under the auspices of the Scottish Committee against Malnutrition, which was formed a year ago by a group of doctors. There will be an afternoon and evening session and it is hoped that Sir Robert Greig, D.Sc., will take the chair. Sir John Orr, F.R.S., director of the Rowett Research Institution, Aberdeen, will be one of the speakers. The main subjects for discussion will be existing nutritional conditions as compared with minimum health requirements, and malnutrition as it affects education. Further information can be obtained from the hon. secretary, 111, Trinity Road, Edinburgh.

SECTIONS OF SERVICES AND TROPICAL MEDICINE AND PUBLIC HEALTH AND HYGIENE

At a joint meeting of these sections, with Lieut.-General Sir WILLIAM MACARTHUR in the chair, a discussion was held on

Leptospirosis

Prof. L. S. P. DAVIDSON (Edinburgh) said that of the 248 accurately diagnosed cases of Weil's disease in Great Britain, 109 have been in fish workers. Furthermore, serological tests of 210 apparently healthy fish-workers showed that 24·3 per cent. had been infected, whereas tests of 406 controls not engaged in this industry were all negative. Infection takes place in three grades: (1) mild with symptoms insignificant or absent, (2) moderate with influenzal symptoms and no apparent jaundice, and (3) severe. The illness begins suddenly with headache, vomiting, generalised muscular pains and fever. Conjunctivitis ("pink eye") and albuminuria with cells and casts are helpful in diagnosis, but jaundice rarely appears before the third day and a diagnosis of influenza is usually made. If jaundice has not appeared by the second week the case is mild and symptoms rapidly abate. In moderate cases fever declines during the second week but jaundice and toxic nephritis are more prolonged. In severe cases convalescence may be long and there may be a secondary rise of temperature during the third week. In unfavourable cases jaundice steadily increases, the urinary output falls, blood urea rises, hæmorrhages take place, and the falling blood pressure and mounting pulse indicate the gravity of the situation. In the Aberdeen series the mortality was 5·7 per cent., about half that in Holland, and the favourable figure was probably due to the high incidence among healthy girls in the fish industry. The prognosis becomes progressively worse with increasing age and particularly in alcoholics, fatal cases usually die between the eighth and tenth day. A neutrophil leucocytosis of 10,000–30,000 is characteristic, and in severe cases anæmia and thrombocytopenia may be marked. The icterus index is raised and the blood urea usually increased high values being of serious significance although cases can recover despite a high blood urea. In Aberdeen 10 per cent. of cases showed evidence of meningitis but all recovered, the protein of the spinal fluid was increased, there was a pleocytosis, at first polymorphonuclear and later becoming lymphocytic, specific agglutinins were demonstrated in the fluid in each case but in no instance were leptospiræ isolated. Antileptospiral serum in doses of 10–20 c.cm., repeated in four to six hours as required notably reduce toxæmia and mortality when given early but after the seventh day the beneficial effects are less marked. Alkaline mixtures are of value for the gastritis and to facilitate urinary excretion. In view of the hepatic and renal damage fat and proteins are restricted and a diet rich in carbohydrates is given, plenty of fluid with glucose seems to be beneficial. Simple precautions that were suggested to the fish industry in 1934 appear to have been disregarded.

Dr. JOHN SMITH (Aberdeen) discussing laboratory diagnosis said that during the first week of the disease the serum can be tested for agglutinins and the clot inoculated into guinea-pigs or culture medium for isolation of the organism. During the second week the agglutination and lysis tests are valuable while from the second to the fourth week organisms may be detected directly or by inoculation in freshly passed urine. He has found leptospiræ in patients' blood by guinea-pig inoculation in all cases up to the fourth day, but only in exceptional cases after the seventh or eighth day. Agglutination reactions are negative before the third day but positive in all cases by the ninth day. In only three instances were leptospiræ isolated from blood showing agglutinating power, but in these cases the titre was 1–30 or less. In four cases when first examined between the fifth and eighth day neither organisms nor agglutinins were demonstrated and such cases may be misleading without further examinations. Leptospiræ were never recovered from the urine during the first week, the maximum success (21·5 per cent. positive) being obtained in the third week, and all were negative again after the fourth week. Agglutinins, probably excreted in association with euglobulin, are sometimes demonstrable in the urine of convalescent patients. Many years after infection cases may still have high agglutination titres in the blood, 15 out of 47 fish workers who had a history of jaundice gave a positive test, 18 out of 48 who had only suffered from a febrile illness were positive, and 18 out of 145 with no history of disease were found to have positive titres. It seems impossible, he said, to keep the premises free from rats but washing down each morning with a hose, the use of hypochlorite disinfectants and greater cleanliness would reduce the incidence of the disease in fish workers.

Dr. J. M. ALSTON (London) discussed the cases seen during the last five years in London sewer workers, the therapeutic effect of antiserum and the prophylactic measures employed. Each worker is given a card drawing attention to methods of hygiene and the importance of proper treatment for cuts and minor injuries. In the event of any illness the card can be shown to the workman's doctor, so that the possibility of Weil's disease may be realised, and this results in men being sent earlier to hospital. Errors of diagnosis by agglutination reaction in cases that have previously received antiserum seem improbable since rabbits given antisera show a rapid fall in titre below the theoretical values that might result from the doses given. False positive reactions may be obtained in the macroscopic agglutination test where formolised antigen is used.

Dr. T. FERGUSON (Edinburgh) said infective jaundice was made notifiable in Scotland in 1924 following an outbreak among miners in East Lothian. Some 558 cases have been notified but many of these, particularly the earlier ones were found to be catarrhal jaundice, although more than 200 cases of Weil's disease were confirmed. Of the latter 9 were children, probably infected in rat-infested streams, of the remainder 62 were coalminers from wet rat-infested pits especially in Lanark, Fife and the Lothians, 92 were fish workers in Aberdeen, 9 were sewer workers, and several were farm workers. In 1926 a departmental committee set up by the Home Secretary reported that Weil's disease might properly be scheduled as an occupational disease under section 43 of the Workmen's Compensation Act subject to certain conditions, the chief of which was that the diagnosis should be confirmed bacteriologically or serologically. So far the disease has not been added to the schedule but a decision of the court of session

in Scotland in 1926 held that it may be regarded as an industrial accident, and as such is covered by the Workmen's Compensation Act.

Dr. F. MURGATROYD (London) thought anti-leptospiral serum ought to be given immediately there is reasonable probability of Weil's disease even while awaiting laboratory confirmation, as in the early stages it is impossible to forecast the course of the infection. Suggestive clinical features are muscular tenderness, conjunctival injection and polymorphonuclear leucocytosis, particularly in those exposed to risk of infection. Syndromes with influenzal, meningeal, pulmonary or even abdominal symptoms have occurred and consequently in any obscure fever Weil's disease should be considered. In isolating leptospiræ from the urine by animal inoculation or culture greater success is obtained if the urine is first made alkaline by giving the patients alkalies, as the organism appears to die rapidly in acid urine. Comparable to this is the fact that in Queensland the epidemics of Weil's disease among the cane-cutters arose chiefly after the heavy rains which reduced the normal acidity of the soil and so assisted the survival of leptospiræ deposited by the rats. As a method of prophylaxis vaccination appears successful in animals but less satisfactory as a practical procedure for man.

Dr. R. D. STUART (Glasgow) said that in the West of Scotland miners, tripe-scrapers and sewer-workers are the groups chiefly affected. The incidence in miners appears to be about 1·5 per cent., but there is evidence to suggest that considerable epidemics have occurred in certain pits. Recently the disease has been found among labourers in the beet-fields in West Cork. Among tripe-workers the cases were mainly mild but all the illnesses were severe among the sewer-workers. As the majority of cases are misdiagnosed in the early stages the occupational risk should be more widely recognised and all "atypical influenza" cases considered suspect. Where infection is localised and severe, as in sewer-workers, vaccination should be considered, and for all cases anti-leptospiral serum should be immediately available.

Dr. J. J. PATERSON (Maidenhead) asked how the leptospira gained entrance to man. Dr. P. H. MANSON-BAHR (London) said the spleen is not usually enlarged in Weil's disease; he also suggested rubber gloves to protect the fish-workers. Prof. J. W. MCNEE (Glasgow) thought that during the late war infection of the soldiers took place through the alimentary tract. He has not found the spleen enlarged, and he said that hæmorrhagic herpes, when present, is a valuable diagnostic sign.

Professor DAVIDSON replied that fish-workers are probably infected through abrasions on the hands but he does not think gloves would be feasible. He agreed that splenomegaly is not a feature of the disease. Dr. Smith followed Schuffner's technique in the agglutination test; for the detection of the organism itself he preferred animal inoculation. He suggested that cases might be looked for among the fish-workers of Grimsby and Hull. General MACARTHUR, closing the discussion, said that more careful examination would reveal a greater proportion of cases without jaundice, as they are probably now being overlooked. Jaundice is no more necessary for the diagnosis of Weil's disease than is a rash for the diagnosis of typhoid.

Sero-Diagnosis of Enteric Fevers

Lieut.-Colonel J. S. K. BOYD (R.A.M.C., London), a short paper, pointed out that the usual serological methods for the diagnosis of enteric fevers are not entirely satisfactory. In subjects previously inoculated with typhoid-paratyphoid vaccine various febrile conditions may produce anamnestic rises of H-agglutinins indistinguishable from those due to actual infection, while in true infections the O-agglutinins, although more specific, sometimes develop so sluggishly that a diagnostic rise is not obtained. Tests for Vi-agglutinins, only applicable at present to *Bact. typhosum* infections, were originally complicated owing to instability of the antigen, but an alternative technique has now been provided by the discovery of strains of *Bact typhosum*, devoid of H- and O-antigen and possessing only Vi-antigen, which can be preserved as standardised formol suspensions. Vi-agglutinins have an important diagnostic significance in the early stage of infection but after the first week they disappear in many cases; they are also important in the detection of permanent carriers but may be absent in convalescent carriers. An important advance is the discovery of bacteriophage having a specific action on virulent strains of *Bact typhosum*. Four serological types of such Vi-phage have been differentiated, one of which, type II, readily becomes conditioned specifically against various strains of *Bact typhosum*; in this way thirteen phage-types of *Bact typhosum* have been distinguished. These phages offer a simple means for typing unknown strains; a number of spreads on agar plates of the bacterium to be tested can be spotted with drops of the various conditioned phages in standardised dilution and the specific lytic effect observed. The phage type of the bacterium remains constant, being unaffected by passage through man, experimental animals or culture, and the test is of value, for example, in linking up an outbreak with a particular carrier, or in determining the source of an individual infection.

Dr. R. D. STUART (Glasgow) asked whether continued fevers in India due to salmonella infections might not give confusing O-agglutination results, and Prof. C. P. BEATTIE (Iraq) stated that O-agglutinins may be found up to a titre of 1 100 in normal persons and may also develop after T.A.B. inoculation. Dr. P. H. MANSON-BAHR (London) said that during the war the H-titre in inoculated persons was found to rise during an attack of malaria. Dr. J. M. ALSTON (London) asked whether virulence varies with phage-type and whether supplies of bacteriophage are available and easy to maintain.

Replying, Colonel BOYD said salmonella infections are relatively unimportant as they are few and far between in India. He agreed that O-agglutinins, and sometimes Vi-agglutinins, may develop after T.A.B. inoculation. Phage-types of *Bact. typhosum* have not shown any antigenic differences in animals. Phage is easily propagated and preserved, and only minute amounts are required for a test.

A popular lecture, illustrated by lantern slides, was given in the afternoon by Dr. P. H. MANSON-BAHR entitled "Aberdeen's gift to tropical medicine—Sir Patrick Manson."

" At Birmingham station I became a modern Englishman, enthusiastically proud of modern England's science and energy; that station alone is enough to make one proud of being a modern Englishman. Oh, what an idea does that station, with its thousand trains dashing off in all directions, or arriving from all quarters, give of modern English science and energy."—GEORGE BORROW, Wild Wales, 1862.

FROM D P M

I

WHAT with the advance of scientific and the decay of clinical medicine the only refuge of the patient nowadays seems to be Christian Science Laboratory workers have certainly come into their own in this generation, and the result has been the coining of the phrase "clinical material" I doubt whether it makes for good medicine to think of people in this light, I fancy it must have been responsible for the experience of rather a weedy youth I know who went into hospital to have a pain in his belly investigated He was there four days and suffered the following traumata two barium enemas and several of the ordinary variety, a barium meal, a pyelography, a test meal, the tube being passed not too cleverly by the nurse, and two or three blood examinations, the blood being collected not too cleverly by the house surgeon And then of course there was the psychic trauma of the bill He went in weedy and came out looking like a weed which has attracted the unfavourable attention of the gardener I am not saying that the tests were unnecessary, though most of the results were conflicting, they served to clear the ground, but I do suggest that they might have been spread out a little and conducted with more humanity The distinguished laboratory and radiological workers who had charge of this bit of clinical material might have looked in now and then to see whether the victim was equal to the next assault Or just to pass the time of day

* * *

Why is clinical medicine at such a discount today? In many fields the criterion of skill has become, not a capacity to make the patient comfortable, but a capacity to pass examinations—surely an extraordinary standard Unfortunately it is a standard which has been adopted largely in the public services, where lay committees have no guide to ability other than a string of letters, and no first hand knowledge of the people they are appointing It comes about, in these services, that promotion depends upon the number of qualifications, much as promotion for a policeman depends on the number of convictions he secures Under this system honest doctors find themselves collecting degrees with the abandon of a boy-scout collecting badges Any number can play at that game, and before you know where you are, M R C P's are three a penny A harmless enough pastime, some say, but the trouble is that a man who is continually working for examinations has less time to be a good, observant considerate doctor He is continually hurrying away from his patients to get at his books Of course if he succeeds in his design this does not matter very much he is made a superintendent and never practises medicine again He spends his life wrestling with laundry machinery drug bills, lavatory accommodation and air raid precautions What a fate for a promising young doctor! Still once he has got to the top he is out of mischief, it is while he is climbing that he is a menace Fortunately there is always a residue of doctors too wily or too lazy to take the bait The patients like having them about

* * *

Visitors to institutions for mentally defective children walk through two wards as a rule before uttering their slogan "What you need is a lethal chamber" Of late they have been able to vary it with another agreeable formula "What you need is a well placed bomb"

There is a working chance that their second suggestion may be put into practice, since mentally defective, unlike physically defective, children will not be evacuated in case of war It seems there is nowhere to put them This is bad luck for them, because they are as easily frightened as normal children and rather less easily reassured The historical attitude of most people towards the fate of mentally defective people strikes me—nowadays—as odd At one time I shared their opinion and advocated euthanasia with the best, but that was before I had had much to do with mentally defective patients Even after a month or two in the wards I was pretty cocksure, but little by little I found where I was wrong The easy superiority of the eugenist deserted me, for I found that I was dealing, not with regrettable accidents but with people—and uncommonly nice people at that

After five years of their society—and the time has been spent among low grade defectives, idiots and imbeciles—I know that if someone presented me with a fine new lethal chamber and authority to use it I should have extreme difficulty in choosing even one victim On what grounds ought the choice to be made? Mere lack of intelligence seems a dangerous standard Many high grade defectives—feeble minded patients and the more able imbeciles—would not be noticeably deficient if placed among simple or savage people, they would do pretty well It seems unreasonable to say that if they had been born scions of a race of savages they would be fit to survive, but that having cropped up in a civilised country they merit death

Moreover it is hard to be sure that the value we set on intelligence is justifiable Intelligence is all very well in its way, it is a useful and sometimes even an agreeable quality but it is only one human quality among many, there is nothing sacred about it Many other qualities have as much, if not more, social value—humanity, candour, reliability thoroughness, to name a few Mentally defective patients often score over normal people in just such attributes, most of them are kindly, innocent easily contented, easily amused and willing to work endlessly at a dull job without losing interest Of course there are exceptions, there are cross grained, difficult, hysterical and deceitful patients just as there are normal people with similar defects of character, but on the whole they are good citizens

The favourite argument for euthanasia, however, is that the mentally defective person cannot earn his keep—he is an economic drag on society and therefore useless This seems an unbalanced argument, for who is useful otherwise than relatively? Who is indispensable, except to himself? Stella Benson summed up human value when she said "An un

natural accident is happening to a noble and unreplaceable cockroach—me!"

The most able of us is no more than a temporary stop-gap, society will get on well enough without us when the time comes. But apart from that, how many people are really as valuable to society as a mentally defective patient contentedly making rugs or shoes or furniture in an institution? How does one assess the social value of a leisured woman living at the expense of a wealthy husband? Or of an impecunious neuropath supported by his friends? Or of an idle young man who spins out his education interminably and never qualifies for a profession? Or of artists indulging their creative instinct gloriously, openly contemptuous of the opinions of society, and anxious only to serve an animistic conception called art? As far as I know the lethal chamber has not been recommended for any of these

The truth is that when it comes to picking our friends we care very little about either intelligence or usefulness—we pick them for more human qualities, often for the qualities found so commonly among the mentally defective. Probably the reason that so few people number certified mental defectives among their friends is that they have no opportunity of meeting them socially. As far as I can see the only patients who would benefit by euthanasia are those helpless idiots who can do nothing for themselves and who are miserable in addition. There are not a great many of these available.

* * *

This war-today-and-none-tomorrow system under which we are living must have curious effects on the endocrine secretions; some of our keener laboratory workers are probably measuring them by this time. Just as the tide of adrenaline has surged through our blood-stream someone in Europe begins another conversation, and the tide is turned off at the main, giving place to relief tempered by a flat-soda-water feeling; no sooner has normal life recovered its true importance than we are called upon to face another crisis. The pathetic speed with which we make the adjustments suggests the fancy that we ourselves are the victims of some super-laboratory-worker engaged in a nicely graded series of experiments. It is not difficult to picture mankind as a group of protozoa under the microscope; someone introduces a drop of weak acid under the coverslip and we flee from it in an angry tide, then he changes the reaction and we flow back blindly, obeying a simple chemical change.

European politics in the last year have become too fantastic for parody, and the swing of opinion in this country has had its amusing side too. Two years ago most of us believed that war should never again be regarded as an argument; intellectually, perhaps, we believe it still, but we have been gradually cozened by changing circumstances—by an alteration in the reaction of the fluid if you like—into feeling it is the only argument left to us. Psychologists say that to be able to forgo without fuss is the hall-mark of adult behaviour, it is also the usual behaviour of very simple animals like the amœba. After centuries of evolution, then, we can boast that the best of us are prepared to submit to our fate as meekly as our first ancestor. We don't seem to have put in the time very well.

Quarterly Journal of Medicine

THE July issue contains the following papers.—

THE CEREBRAL BLOOD-FLOW IN ARTERIAL HYPERTENSION, ARTERIOSCLEROSIS AND HIGH INTRACRANIAL PRESSURE. By Denis Williams and William G. Lennox (Boston). Arteriovenous oxygen and CO_2 differences (using internal jugular vein blood) were determined in groups of patients with these conditions, and in patients with normal intracranial circulation. With one exception no significant abnormalities were found in any group. This indicates that in arterial hypertension (even in one case with severe congestive cardiac failure), in raised intracranial pressure (even in comatose cases), and in cerebral arteriosclerosis, the cerebral blood-flow remains within normal limits. The exception is the cerebral arteriosclerosis group, in which the mean cerebral blood-flow, though within normal limits, is low, indicating mechanical limitation of the vascular bed.

THE EFFECT OF PITUITARY THYROTROPIC EXTRACT IN SUBJECTS WITH LOW BASAL METABOLIC RATES. By E. P. Sharpey-Schafer and I. Schrire (British Postgraduate Medical School). Intramuscular injection of pituitary thyrotropic extract produced clinical changes, increased creatine excretion, and increased basal metabolic rate in every one of twenty-two normal subjects, and in five subjects with various endocrine disorders. It was without effect in three myxœdematous patients and one cretin, also in three subjects with low basal metabolic rates, but without other myxœdematous features. These three all showed evidence of hypogonadism, one of them was proved by biopsy to have a normal thyroid gland.

THE TREATMENT OF CHRONIC HYPOPARATHYROIDISM. By Ian A. Anderson and Alexander Lyall (Aberdeen). Calcium and phosphorus balance experiments on three cases of postoperative hypoparathyroidism are reported. In all three the serum calcium could be raised to and kept at a normal level by a diet low in phosphorus, supplemented by a large addition of calcium (as calcium lactate). A similar calcium intake, without restriction of phosphorus, was without effect. The mechanism of the effect, which is of obvious therapeutic value, is discussed.

THE DIFFERENTIAL DIAGNOSIS OF FORMS OF BASOPHILISM (CUSHING'S SYNDROME), particularly by the Estimation of Urinary Androgens. By A. C. Crooke and R. K. Callow (London Hospital and National Institute for Medical Research). Four cases are described. In two a malignant adrenal cortical tumour was found, after being palpated in one case and demonstrated in the other by radiography after perirenal air sufflation. The urine of these two gave high values in the colorimetric assay of 17-ketosteroids or in the biological assay of androgens, that of the other two, in whom no adrenal tumour was present, gave low values. These urinary assays are claimed to give valuable help in the differential diagnosis.

THE CAUSATION OF THE LOW BLOOD SUGAR IN CŒLIAC DISEASE. By Theodore Crawford (Glasgow). The blood sugar curves following intravenous injection of 0·5 g. glucose per kg. body-weight, in twelve cases of cœliac disease, were similar to those in normal children, eleven of the cases gave low curves after oral administration of glucose. This points to defective absorption from the gut as the explanation of the low blood-sugar levels in this condition. Six of the cases also gave normal blood sugar curves after intravenous injection of insulin.

RHEUMATIC HEART-DISEASE AS MET WITH IN HOSPITAL PRACTICE IN CEYLON. By P. P. Fernando (Colombo). Post-mortem findings over a period of 3½ years are compared with statistics from Guy's and St. Mary's Hospitals, London; the incidence and general features of rheumatic carditis are about the same in the Ceylon series as in those from London. A survey of the clinical features of the rheumatic infection, as seen in one group of wards in the same period, shows no important difference (except the absence of nodules in Ceylon) between the disease as seen in Ceylon and the disease as seen in temperate climates.

THE LANCET

LONDON SATURDAY, SEPTEMBER 2, 1939

A PEACE OF UNDERSTANDING

We have been witnessing a political degradation The German people—our cousins in blood, our fellow-workers in science, and often our friends—have been drilled to believe evil of their neighbours First the Czechs and now the Poles are accused of malign intentions against the Reich, and their evil mounts higher and higher according as the German preparation for their destruction advances When such accusations are made by individuals psychiatrists call the process "projection" They regard it as a dangerous symptom, while jurists have always held that such behaviour should be handled by the police and with due process of law Likewise the world today, less inclined than formerly to be lenient to the antisocial tendencies of nations, holds that if a nation goes wrong in this way it should be checked

The knowledge lately gained of the disorders of the mind may help in the restoration of order in Europe When a person attributes to another the evil within himself his purpose is not simply to preserve the illusion that he is blameless and peaceable, it is also, unconsciously, to preserve a cherished object or ideal from attack We must recognise that in the German people today there are forces of devotion, loyalty and passion which rise above the self and demand an allegiance superior to the claims of comfortable living Unfortunately, high ideals in an individual or nation may be associated with serious antisocial tendencies We are coming to recognise in our patients the complicated inter-relation of these two elements, and in national affairs we shall find it no less difficult to give full weight to the power of knowledge, for we must first put our own fears and counter-hostility aside Yet if we want truth and peace and liberty to think we must give ourselves to the task which truth and peace and liberty of thought demand of us

Nations judge themselves by their war aims, posterity judges them by their manner of offering, making, accepting and keeping the terms of armistice and peace A brutal and antisocial force is at work in Germany today, destroying the peace of Europe, and, whether we know it or *ignore* it, we too are at the bar of History We in England are united as seldom before in a common cause—to stop power being used for private ends We have that access of power, as for the moment has Germany, which comes from the canalising of action in a single purpose But its strength will be largely wasted, as was that of the last war, unless we use it rightly Unless we keep the aim of our struggle and the conditions of peace in full view all the time we shall be like harassed relatives holding down a dangerous patient till from exhaustion he submits—for the moment As psychiatrists we have given up the use of chains, though not always the use of locks, as peace-holders of Europe we must avoid the notion, too prevalent a quarter-century ago, of crushing Germany out of existence or of hanging the Kaiser As psychiatrists we know the domestic war of nerves to be the climax of a prolonged inner conflict and disquiet in the patient, and if we are good psychiatrists we shall recognise the harm done by our own mistakes To deal with the disruptive force of this kind of aggression we need a moral courage to face the evils in our own human nature

Doctors have little to do in war except to mend the injuries done by aggression, but they may take comfort from the belief that their discoveries can do more than anything else to remove the burden of war Today such a boast may seem strange, yet now of all times it ought to be made true For we must not forget—nor let others forget—what we have learnt from clinical work The physician's power to control disorders of the mind depends on the patient recognising him as an open-minded and human creature who can be trusted to deal with him fairly Our propaganda will be powerful for peace in proportion as it carries the conviction of our moral capacity to make a good peace A war of silent hate would be long and destructive of our lives and our own ideals The will to achieve a lasting peace must include an open-minded willingness to listen to complaints and meet grievances, remembering that the peoples of Europe will have to live as neighbours to the end of time

MARIHUANA

An old vice in the new world has in the past three years become something of a sociological problem Cannabis indica has been indulged in for thousands of years and under the names of hashish or bhang it is still used extensively in the near east and especially Egypt by the so called criminal classes In India chronic psychoses due to hashish are extremely common In the Bombay mental hospitals[1] last year, cannabis indica psychosis accounted for about 12 per cent of all admissions Lately the vice has spread among lazy and dissolute adolescents in the USSR, the plant having been introduced by way of Turkestan and the Caucasus In Mexico the drug is known as marihuana, a corruption of the Portuguese "marguango" meaning intoxicant Its picturesque synonyms in the United States, whither it is smuggled from Mexico, include muggles, *reefers*, Mary Warner, Indian hay, the weed and tea The hemp plant is cultivated for fibre in the mid West and also grows wild throughout the USA The dried flowering tops are rolled into cigarettes In New Orleans and in other parts of the States pedlars sell these cigarettes in clubs, cabarets, and restaurants The younger generation are apparently the chief smokers and even boys and

1 Annual Report on Mental Hospitals in the Bombay Presidency, 1938, Bombay, 6d

girls pay a nickel for two mootas or marihuana cigarettes and hysterical states known as "laughing jags" are not uncommon. Marihuana in all its aspects has recently been described by Prof. R. P. WALTON [2] His book is the most complete monograph on cannabis indica intoxication and is comparable with MAIER'S [3] study on cocainism, ROUHIER'S [4] on mescalism, and that of TERRY and PELLENS [5] on opium

Marihuana from the psychiatric point of view appealed frequently to the romanticists of the nineteenth century DUMAS, GAUTIER, BAUDELAIRE and DE QUINCY, and such Americans as BAYARD and HECTOR FRANCE have given vivid descriptions of the mental changes induced by the drug Recently BROMBERG [6] has investigated marihuana in New York His study is based on material seen in his capacity as psychiatrist to the Court of General Sessions and the Bellevue Hospital. He is sceptical as to whether marihuana really causes its addicts to commit rape, suicide, and murder, as the popular press in America allege He even casts doubts on the drug's habit-forming capacity Tolerance does not appear to increase, and there are no demonstrable withdrawal symptoms. In 67 cases involving marihuana seen at his court it was found that early use of the drug did not predispose to crime and no single positive piece of evidence showing the relation between marihuana and sexual or violent crimes came to light Countless people use marihuana without developing any observable mental upset and, as is the case with alcohol, the essential factor in the development of a marihuana psychosis appears to be the personality of the patient

The marihuana psychosis occurs in two forms, acute intoxication and a more enduring toxic psychosis Acute intoxication lasts a matter of hours or days Its features are euphoria often associated with anxiety and apprehension, depersonalisation and upset of time appreciation Dance-band musicians are said to use marihuana to produce an apparent slowing of the tempo of their music, thus enabling them to play fast passages easily when improvising on a theme There are feelings of bodily change such as lengthening of the limbs and swelling of the head Sometimes the confusion is associated with visual illusions and hallucinations The toxic psychosis lasts for weeks or months and is often superimposed on schizophrenia or some other mental illness. Indeed, it appears that marihuana is merely a trigger which releases a latent insanity

In the interest which marihuana addiction has aroused in the States credulity appears to have outrun science The press and stage have exploited it and it even formed the theme of a cinema film, Assassin of Youth." To the enthusiasts who see in marihuana the hand of Satan, BROMBERG'S work provides a healthy corrective. The only final conclusion which he allows himself to draw is that marihuana is a sensual addiction in the service of the hedonistic elements of the personality.

MILITIAMEN AND TUBERCLE

THE death of a militiaman from pulmonary tuberculosis, a few weeks after having been placed in grade 1 by a medical board, raises again the question of the advisability of including radiography of the chest in the routine examination of these young men This militiaman was re-examined and passed as fit on joining his unit on July 16, on the 29th he was sent to hospital for two days' observation, after an attack of dizziness; he returned to duty but collapsed during drill on Aug 19, and died almost at once. Post-mortem examination showed extensive cavitation in both lobes of the left lung.

Pulmonary tuberculosis still accounts for about a third of the total deaths of young adults from disease, and the incidence of significant lesions found radiographically in so-called healthy persons is variously reported as from 0 5 to 2 0 per cent. This would mean 1000–4000 out of the 200,000 annual recruits for the militia. In Parliament in June Sir VICTOR WARRENDER [1] said it was beyond the wit of the medical profession to ensure the discovery of latent disabilities before a militiaman is passed into the army, and there can be no doubt that with only physical examination, however carefully carried out, a serious number of cases of early phthisis will be missed Mass surveys in the United States, France and elsewhere have demonstrated that in this respect routine radiography will give a much higher proportion of accurate diagnoses Thus, of some 25,000 candidates for employment in the French state railways in the years 1935–37, about 1·2 per cent were discarded on radiological evidence after being passed as sound on physical examination

The ascertainment of early cases among militiamen is important enough for the recovery of the patients themselves; but it is doubly important for the sake of those with whom they will come in close contact during their training The compulsory medical examination of all prospective state employees in France includes screening of the chest and radiography where the screen findings are suggestive. A similar procedure for militiamen would require a large supply of expert radiographers, and would not provide any permanent record, other than a written report, in every recruit's dossier. The cost of a celluloid film for each recruit would be high, and in a full-sized paper radiogram, which is cheaper, a significant amount of detail is lost through the coarse grain of the paper. As suggested in these columns on June 10 (p. 1330), the miniature radiogram, in which a small photograph is taken of the fluorescent-screen image, combines a high standard of accuracy with a cost of less than a penny per recruit. The miniature radiogram can be examined by the expert at leisure, and four such experts would have no difficulty in dealing with 200,000 recruits a year. The method could be applied even to the flood of

recruits in war-time It is already in use in Germany, largely owing to the technical progress made by R JANKER A satisfactory apparatus, of which the cost is not prohibitive, has been described in THE LANCET by DORMER and COLLENDER,[2] and it would be a wise step for the proper authority to make a close study of technique and working details and to select a panel of diagnosticians—in the first instance to cover future groups of new militiamen, but capable of expansion in the light of experience

ANNOTATIONS

INDUSTRIAL HYGIENE

THE report[1] of the Chief Inspector of Factories for 1938 is coloured by two unrelated facts or sets of circumstances, one being the operation of the new Factories Act 1937 and the other the state of international tension and consequent rearmament Mention is made of a greatly increased demand for defence material of all kinds, of great activity in aeroplane construction, of the building of new ordnance factories and munition works, and of the flourishing state of the iron and steel trades It is pleasing to note that the trading estates established in the Special Areas are developing rapidly At Team Valley near Gateshead, for instance, the number of occupied factories has risen from 29 to 86 during the year with an increase of 1160 workers In Renfrewshire and Wales similar improvements are noted The articles manufactured on these estates are not all of war like intention and the varied list contains light metal goods, food stuffs, motor car bodies and safety glass The variety in manufacture replaces to a great extent the employment on heavy industries on which these areas depended so much in the past Sir Duncan Wilson, the chief inspector, points out that, in welcome contrast to the previous two years, there has been a decrease in the number of reportable accidents, amounting to 7 per cent for fatalities and to 6 per cent for all accidents whereas in the manufacturing industries alone the decreases were 12 5 and 10 per cent respectively In the metal rolling mills the number of accidents fell by as much as 30 per cent, those occurring on power presses by 25 per cent and those due to transmission machinery by 17 per cent, on the other hand the number of accidents on building operations has risen by 20 per cent In spite of the reduction in general accident rates which Sir Duncan suggests might have resulted from the safety requirements of the new act, there is still room for further improvement

The new act has reduced the permissible working hours of women and young persons to 48 per week with a limit of 6 hours overtime in a week and 100 hours in a year—overtime being prohibited for all workers under 16 years of age Previously it had been possible to work a woman or young person 12 hours a week and 600 hours a year beyond the 48 hour week The application of the hours of employment provisions of the act has caused a good deal of confusion in different industries but some firms have been surprised and at the same time gratified to find that with *shorter hours* their production has been as good and their expenses have been lower It is remarkable that employers and employees still have not learned the lesson that long hours of work in many processes *bring* about an actual reduction of output, a point which the Industrial Health Research Board has made year after year in its annual report

Under the new act the certifying surgeon becomes examining surgeon, with increase of duties, responsibilities and fees, and the changes seem to be resulting in an increased sense of responsibility and pride in the importance of the work The innovation of medical record cards to be filled in by the examining surgeons after their examination of young persons has added to the interest of the work and these records, when collated and analysed, will provide the much needed information on the general health of young persons in industry

PRESCRIPTIONS FOR SULPHANILAMIDE

SINCE the Pharmacy and Poisons Act, 1933, came into operation sulphanilamide, under whatever name it is offered for sale by manufacturers, has been added to schedule 4 of the Act This schedule contains the names of substances which may be supplied to the public only on a medicine prescription The addition was recorded in our columns when the notice to this effect was gazetted, but some prescribers occasionally overlook the fact that the prescribing of sulphanilamide is subject to the same legislation as barbiturates Consequently they are apt not to define precisely the number of times the prescriptions may be dispensed It is usual in prescribing barbiturates for the prescriber to indicate the total quantity the patient is to receive, but prescriptions for sulphanilamides often bear the simple instruction "To be repeated" While such an instruction is permissible under the regulations, there is the danger that the patient may use the prescription to obtain supplies in excess of those intended by the prescriber The chemist who dispenses the prescription marked thus is not required to retain it, and it may therefore be taken from one chemist to another If prescribers would indicate the number of times such prescriptions are to be repeated, dispensers would be relieved of a justifiable anxiety when presented with a much thumbed prescription for a schedule four substance

LEPTOSPIROSIS

WEIL'S disease has lately been much in the professional if not in the public eye, for it was discussed at Amsterdam last year and at Aberdeen last month, as reported in this issue, and is the subject of a bulletin of the Health Organisation of the League of Nations[1] The disease has also assumed legal importance and has been the basis of a number of actions under the *Workmen's Compensation Act* Many industrial concerns are now alive to its risks, and the present publicity must lead to more effective steps being taken to minimise them The infection is essentially an occupational one and takes different forms in different occupations The "swamp fever" of Russia and Germany chiefly affects land workers after floods The reservoir of the organism *Leptospira grippo typhosa*, is unknown, but field mice are

1 Cmd 6081 H M Stationary Office Pp 133 2s.

1 *Bull Hlth Org L.o.N.*, 1939, 8, 144

suspected The symptoms are gastro-intestinal, jaundice is absent and the mortality is nil. The type due to *L. canicola* has chiefly been reported in the Netherlands, though recently the serum of a Glasgow tripe-dresser agglutinated this strain. The only known reservoir of this type is the dog The most important type in this country is that due to *L. ictero-hæmorrhagiæ*, the chief carrier of which is the rat In some localities more than a third of the rats are "healthy" carriers excreting the organism in their urine Human infection is acquired through the alimentary tract or by contact from contaminated water or other material It was common on all fronts during the war, and during the last few years it has been found among the fish-workers in Aberdeen, sewer-workers in London and Glasgow, tripe-dressers in Glasgow, coal-miners, and workers in the beet-fields in Ireland, who are probably infected through abrasions of the hands in the same way as are the sugar-cane cutters in Queensland The classical description of Weil's disease gives a false impression of its course, for some 60 per cent. of cases show no jaundice at all Many are mis-diagnosed as influenza, and if a patient presents an acute fever of obscure origin with muscular tenderness, conjunctival injection and a neutrophil leucocytosis, the possibility of Weil's disease should be investigated by bacteriological and serological tests, particularly when there has been any risk of infection Where there is a definite occupational hazard it may be wise to administer antileptospiral serum while awaiting laboratory confirmation.

AGE AND PARITY IN PLACENTA PRÆVIA

FROM an analysis of sixty-nine carefully acquired maternal histories, in which there were seventy-two cases of placenta prævia, Penrose concludes that maternal age and multiparity are both likely to be important factors in the production of this condition [1] If these seventy-two cases had been randomly distributed amongst all the pregnancies which these women had experienced, then the average age at which placenta prævia occurred would have been 29 10 years. The observed average age was in fact 31·86 years, a difference beyond what is likely to be due to chance. Mothers of 35 years of age or more produced twenty-seven out of the seventy-two cases, whereas they would have been expected to produce only fifteen if age had no effect The same form of comparison shows a clear tendency for mothers with a high degree of multiparity to be over-represented in the series; the observed mean birth rank was 3 55 and the expected mean only 2 58 Similarly there were twenty-three observed occurrences of placenta prævia at birth orders of four or more against an expectation of only fourteen Age and parity are, of course, themselves associated, and the number of observations available to Penrose is rather small for the determination of the relative importance of each independent of the other. Using the method of correlation, he finds, however, that multiparity probably has an independent effect though this may be less important than that of maternal age Further subdivision of the observations shows that the mean maternal age for central placenta prævia was significantly high while for marginal and lateral cases it was not abnormal. This observation is confirmed by a further series of cases collected from the Royal Free Hospital. On the other hand the mean number of pregnancies was almost exactly the same in both central and non-central groups Finally, the data gave no evidence that the length of time elapsing between the abnormal pregnancy and the pregnancy immediately preceding it was unduly short in comparison with other pregnancy intervals in the families studied. There was also no obvious tendency for the condition to affect the firstborn. Incidental observations show that the mother survived in sixty-seven of the seventy-two cases but the child in only twenty-five instances. Judging from these hospital cases cæsarean section appears to be the most satisfactory form of treatment from the point of view of the child, and scarcely less favourable than version and extraction from the point of view of the mother.

ALCOHOL IN AIR FORCES

THE anxiety expressed in other countries about the prevalence of alcoholism among air-pilots may have led to doubts about the state of affairs in this country. During the war of 1914–18 heavy drinking became almost a convention among flying men, and this convention lingered afterwards It had arisen at a time when the inferiority of our machines compared with those of the enemy was felt to justify an infusion of Dutch courage, but now that its underlying cause has been removed it exists no longer For junior officers of the Royal Air Force, wine bills are strictly limited; there are non-treating orders in messes, bars are not open for alcoholic drinks in flying training schools until the evening, and drinks may not be consumed in private rooms To break the first two of these rules is a court-martial offence In the past few years, too, the mental attitude of officers towards drink has changed The Service has become a career and permanent commissions are hard to get. Promotion has depended upon examinations, specialisation, linguistic skill and staff-college work, as well as ability at flying and games. Heavy drinking cannot and does not mix with these, and the routine medical examinations serve as a continual check which reveals any incipient physical or emotional disability

THE TRELOAR MARINE HOSPITAL

Sir Alexander Maclean's noble gift will make it possible to provide the cripples' hospital at Alton with a complete seaside annexe at Sandy Point, Hayling, where 120 children will continue their recovery from poliomyelitis under ideal conditions. Pioneer work has already been done there with the wattle hurdle and the glowing brazier on the sea-beach, but these were insufficient to deal with last year's epidemic of poliomyelitis, when Sir Henry Gauvain was fortunate in getting many of the cases at a stage when orthopædic treatment is most beneficial After an initial period of entire rest, the patient, still paralysed and immobilised in splints, is transferred to the pool where the splints are removed when the limbs are supported by water. There being no friction, exercise is practically effortless It was the American experience with such pool treatment that determined the donation; there, skilled technicians enter the pools with the patients and carry out the prescribed movements. In the new pool at Sandy Point the buoyancy of the sea-water may produce results which have not been possible as yet elsewhere The sea-water pool, 30 ft. by 15 ft with water at a temperature of 92° F., will have under-water illumination to assist the exactitude of the treatment A super-saline pool will be used for cases of osteomyelitis with discharging sinuses A current pool will provide water massage for scoliosis and polio cases A super-warm pool, with a temperature not less than 100° F., will offer sedative treatment for spastic paraplegia, and air bubbles can be utilised in a modified Hubbard pool.

Acute polio cases will now be admitted direct to Sandy Point hospital and treated in an isolation pavilion which will have a room for cases of respiratory failure, where there is also swallowing difficulty the patient can be placed prone with lowered head and an electrical sucker to remove mucus from the glottis The big pool room will have folding doors which can be thrown open towards the sea, patients will be transferred from the wards by trolleys and lowered by hydraulic cranes on to floating plinths After removal from the water they will be dried by a combination of hot air and towel friction and then have treatment by light, radiant heat or massage Education will be available for all those undergoing long treatment

LIGHTENING OUR DARKNESS

THE demands of A R P have created a new use for complementary colours A red light is completely invisible when looked at through blue glass For complete suppression of the light, it is essential that the tinting should be very precise A practical cellulose acetate derivative called Rhodoid has been developed by May and Baker Ltd It should prove of great value for darkening windows of hospitals and other buildings where curtains would be neither practicable or desirable Samples of rhodoid have been tested at the Government's building research station at Watford, and at the Bradford Royal Infirmary Here the A R P committee fitted one room with lamps covered with pink tinted rhodoid shades A similar tinted pale blue covering to the windows made the pale red light from the lamps completely invisible from outside The material is fixed permanently to the inside of the windows by means of an easily applied adhesive When there is no danger from an air raid, windows can be left open in the usual way and so admit ordinary daylight which practically eliminates the blue tint At night, with all the lights on and no opaque covering across the windows, not a glimmer can be seen from outside The windows are quite black as though boarded in By day or night, if warning of an air raid is received, all that is necessary in any building equipped in this way is to close the windows and fasten the pink lampshades Activities can continue inside uninterrupted The system should be of particular value for operating theatres where by means of special wiring arrangements illumination can be instantly switched from white to pink as soon as a warning is heard We understand that a similar system is in operation in parts of St Thomas's Hospital, where tinted bulbs are used

CONVULSIONS IN CHILDHOOD

IN his latest contribution to the study of convulsions Peterman[1] of Milwaukee describes his investigation of 1000 cases Taking the causes in chronological order he finds that birth injury accounts for 15 5 per cent The next hazard is the acute infections, and of Peterman's series respiratory infections and infectious diseases, not including meningitis, encephalitis and gastro enteritis, were responsible for 14 per cent The pathological basis of these convulsions is not clear High fever alone may be responsible, and it is recognised that convulsions associated with fever may recur at irregular intervals for the first two or three years of life, but not after that Between six months and three years the possibility of spasmophilia arises, and 8 9 per cent of Peterman's cases were put down to rickets When this age-period is passed idiopathic epilepsy comes to the fore, and accounted for 23 6 per cent of Peterman's cases Of the remainder, 12 7 per cent are listed as miscellaneous, and 5 3 per cent as "cause not established" Peterman suggests that some of the convulsions included in this last group were due to dural sinus thrombosis following gastro enteritis, but it is surprising that alimentary disturbances occupy such a small place in his series What are termed "terminal convulsions" are not included, and this may cut out the type of case in which gastro enteritis has seemed to play a part He gives no support to the belief that teething, worms and adhesions of the foreskin cause convulsions

In treatment Peterman maintains that hot baths or hot packs do more harm than inactivity As emergency measures he favours cold packs or cool sponges if there is high fever, and a cool hypertonic saline enema, such as a 25–50 per cent solution of magnesium sulphate Next in importance Peterman places the prompt administration of chloroform, which he regards as safer than morphine or opium or even chloral He regards lumbar puncture, if facilities permit, as of great value not only in treatment but also in diagnosis Every convulsion produces serious injury to the brain and the aim of treatment is to stop the convulsion as soon as possible and prevent recurrences A point often overlooked is that after a convulsion a child should be treated as in every cranial injury with absolute rest in bed for several days For recurring convulsions Peterman advocates phenobarbital as the drug of choice, and for idiopathic epilepsy he reiterates his belief in a ketogenic diet Here he enters controversial ground

TRANSFERS DURING DOCTORS' ABSENCE

THE Minister of Health has been asked by the Insurance Acts Committee to arrange for the readmission to the lists of practitioners who are called up for service during peace time under the Reserve and Auxiliary Forces Act, 1939, of insured persons who transfer during their absence The Minister has accordingly issued a regulation that comes into force at once by which, on the return of practitioners from service such insured persons will be re transferred without application or notice on their part On receipt of a request from the returning practitioner the insurance committee will inform the insured persons of the intended re transfer and if they do not object within 14 days the re transfer will be made Copies of the regulation and an explanatory letter have been sent to all insurance practitioners and the attention of those called up under the act is drawn to the importance of notifying the insurance committee concerned without delay of their intended absence (and the reason) and of their deputising arrangements The new regulation will apply only to what are known as end of quarter transfers, transfers because of permanent removal and those with the consent of the practitioner concerned are specifically excluded

THIS WEEK'S ISSUE

Difficulties of publication arising out of the international crisis have made it necessary to rearrange the contents of this week's issue of THE LANCET, *and the Proprietors express to subscribers their regret at the omissions required The journal is being printed at Aylesbury, and urgent communications may be addressed to the Editor at Messrs Hazell, Watson & Viney's printing works there But the London office remains open at 7, Adam Street, W C 2 (Tel Temple Bar 7228–9)*

1 Peterman M G, *J amer med Ass* July 15 1939, p 191

SPECIAL ARTICLES

EMERGENCY NOTICES

ISSUED BY THE CENTRAL EMERGENCY COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION

1. *In time of war the Central and Local Emergency* Committees established by the British Medical Association will be responsible to the Government for the supply of medical personnel for the fighting forces and for the civilian population.

2 The allocation of practitioners for duty at first-aid posts is now complete. The appointment of practitioners to the Civilian Hospital Service, classes A and B, is practically complete, and any member of a hospital staff not liable to call for other duties who is uncertain as to his position and duties in the event of war should immediately communicate with the Group Officer for his area

3 Demands for medical personnel for the Services will, as hitherto, come from the department or service concerned direct to the Central Emergency Committee, which will allocate a quota of the demand to each local emergency committee, having regard to, inter alia, the movements of the civil population Practitioners who have intimated their willingness to undertake national work of one kind or another but who have not yet been allocated should wait until they are approached by their local emergency committees

4. After the outbreak of hostilities any practitioner in an evacuation area who, as a result of evacuation, is rendered unemployed and is willing to undertake work in a reception area should register with the secretary of his local emergency committee and request that his name be added to the reserve list which is being maintained by the Central Emergency Committee at this office

5 After the outbreak of war and the putting into operation of the official evacuation schemes, local emergency committees in reception areas will estimate the additional requirements in their areas for medical personnel of all kinds and will communicate their needs to this office.

6 There are now in the possession of all local emergency committees in England and Wales supplies of the following three documents:

(1) Memorandum of Ministry of Health explaining procedure for medical certification in connexion with payment of injury allowances in time of war.

(2) A book of first certificates to be used by medical practitioners in certifying war injuries.

(3) A copy of a memorandum of advice by the Registrar-General to medical practitioners on the methods of death certification in respect of civilians killed by enemy action.

Local committees have been requested to distribute a set of these documents to every medical practitioner in their areas if and when a state of war is officially announced or on any earlier intimation from this office

7 In reference to the certification by medical practitioners in connexion with the payment of injury allowances in time of war, referred to in 6 (1) and 6 (2), medical practitioners should give the necessary certificates to the appropriate injured persons applying to them without charge, whether those persons are insured persons or not The Association has informed the Government that it will advise the profession to undertake this service in the public interest. Although the great majority of these certificates will be issued by hospital authorities some patients will no doubt apply to their own practitioners for them and every practitioner remaining in private practice should have a book of certificates in his possession Arrangements for further supplies will be the subject of a further announcement.

8 This paragraph applies only to the following areas.

All English counties, except London and Middlesex, and the following county borough councils: Barrow-in-Furness, Bath, Blackpool, Bournemouth, Brighton, Burton-upon-Trent, Canterbury, Carlisle, Chester, Eastbourne, Exeter, Gloucester, Hastings, Ipswich, Lincoln, Northampton, Oxford, Reading, Southport, Worcester and York.

These are areas to which will be moved numbers of pregnant women from evacuation areas Their medical officers of health have been asked now to consult with the local emergency committees on the question of the available obstetric personnel. Local emergency committees are asked, after consultation with the medical officer of health, to make any necessary recommendations for allocation, and, if it is agreed that the number of obstetric consultants available in the area is insufficient, *now* to make the appropriate request to the Central Emergency Committee for additional obstetric personnel.

9. The Association has agreed with the Ministry of Health the terms of the financial arrangement for the medical treatment of children evacuated to reception areas under the Government's scheme In this connexion the following communication has been dispatched to all medical practitioners in reception areas:

"This is an important communication addressed to every *medical practitioner in a reception area*, that is, in an area to which there will be official evacuation of children under the Government evacuation scheme. Agreement has today (Aug 27) been reached between the Association and the Ministry of Health as to the financial arrangements for the medical treatment of children transferred to reception areas under the Government scheme. The arrangement applies to each child who is billeted upon an householder, not accompanied by a parent. It does not apply to children accompanied by parents.

"There will be placed at the disposal of each local emergency committee in a reception area a sum of money to meet the cost of the provision of medical attendance This sum will be calculated at the rate of 10*s* a year for each unaccompanied child transferred under the scheme This money will be disbursed to practitioners undertaking the treatment of children covered by the scheme on a basis devised and approved by the local emergency committee concerned. The amount paid is intended to cover the cost of attendance and the provision of medicines.

"The main purpose of this letter is to inform you of the fact that this financial arrangement has now been approved and that in respect of unaccompanied children transferred under the Government evacuation scheme payment should be sought, not from the patient or the householder, but from the local emergency committee.

"*Local committees have today* been asked immediately to devise their schemes of distribution and to inform the practitioners of their decisions If you are called upon to treat any children covered by this arrangement before the local emergency committee has communicated its scheme to you, please record particulars of such treatment, including the name and address of the patient."

Local emergency committees will realise that local schemes of distribution should be determined at once It is probable that payments will be made at the end of each quarter. The committee may decide to pay on an item of service basis, within the capacity of the pool, it may decide to pay a quarterly capitation per patient seen, whatever the number of items of

service, the capitation fee being calculated by dividing the number of persons treated into the amount available. If it decides to introduce practitioners, through the Central Emergency Committee, to treat *these patients*, their remuneration in respect of this work should be provided from the local pool. In short, the responsibility for providing an adequate service for these unaccompanied children, and for the distribution of the local pool, rests entirely with the local emergency committees in reception areas to which such children are evacuated.

10. The address of the Central Emergency Committee will continue to be this House—unless and until an intimation is given to the contrary.

British Medical Association House,
Tavistock Square, London, W.C.1

MEDICINE AND THE LAW

Surgical Instrument left in Body

AT an inquest at Weston-super-Mare on Aug. 21 the jury found that a woman aged 66 had died of shock following a severe operation for perforation of the bowel due to the presence of a metal depressor in the abdominal cavity. An X-ray photograph had shown the presence of this piece of metal, an operation had been deemed necessary for its removal. There had been a previous operation on June 8 for removal of a cancerous growth. There seemed no doubt that the depressor had been left inside the patient on that occasion. The first operation had taken place in a private hospital in Bristol. A nurse who was in charge of the operating theatre at Bristol was unable to remember whether she herself or another nurse who was also present had counted the surgical instruments before or after the operation. In the jury's view there had been negligence, not amounting to criminal negligence, on the part of those in charge of the operating theatre, inasmuch as there had apparently been no strict supervision of the instruments. The surgeon who had operated on the first occasion was said to be on his way to America. The jury said it did not want the inquest adjourned in order to hear his evidence.

There have been judicial discussions on the question how far the mere presence of a swab, forceps or other instrument in a patient's body after an operation may be said to establish a prima facie case of negligence against those in charge of the operation. The Latin maxim *res ipsa loquitur*—the thing itself speaks—has sometimes been relied upon. On the other hand an eminent Scottish judge has contemptuously remarked that if that maxim had not been in Latin, nothing would have been heard of it.

Injection from the Wrong Bottle

An inquest at Cromer last week indicated the inadvertent use of a bottle of morphine instead of a local anæsthetic. The jury, returning a verdict of accidental death, added a rider that it might be suggested to the drug companies that morphine should be issued in distinctive bottles.

The deceased woman, aged 25, suffered from advanced tuberculosis in both lungs and was unable to do any heavy work. She became pregnant and her medical attendant, after taking a second opinion, arranged for her to go into hospital to avoid complications. Unfortunately the child was born quicker than was anticipated. The doctor, arriving ten minutes after the birth, found the patient's condition reasonably good but deemed it advisable that she should enter the hospital where she received treatment. An injection was administered on the Saturday. On the Monday an operation was decided upon and Novocain was to be injected. The sister who had prepared the tray on the Saturday had then been to the cupboard which contained two bottles and had taken the right one. On the Monday the bottle containing the local anæsthetic was not in its place in the cupboard. The sister took the only bottle from the cupboard. The mistake was not discovered until an injection of morphine had been given by mistake. The two bottles were similar in colour and size. The two solutions could not be distinguished in colour when in the syringe used for the injection. The injection of morphine accelerated hypostatic pneumonia to which death was due. It was announced that the management committee of the hospital would take immediate steps to see that the bottles of morphine would be distinctive in size and colour.

(FROM OUR OWN CORRESPONDENT)

HUMAN GENETICS

THE seventh international genetic congress opened at Edinburgh on Aug. 23. About 500 delegates were present representing 33 countries. Before the formal opening, the delegates spent two days in London and two in Cambridge, where visits and demonstrations had been arranged for them. A special tour then enabled many foreign members to visit, on their way to Edinburgh, such places as Stratford on Avon, Chester, and the Lake district. At a plenary session held in the McEwan Hall, Edinburgh, the congress was welcomed by representatives of the City and the University, and Dr. F. A. E. Crew, Buchanan professor of animal genetics at Edinburgh, was elected president. The vast scope of the congress is shown by the fact that the section of human genetics was one of nine, and the programme of this section alone included nearly sixty papers. The international high tension led to some modifications, and many were the anxieties of those organising the congress. In its somewhat mutilated form the congress was a good one even by absolute standards.

DIPHTHERIA IMMUNISATION IN GLASGOW

The health and education committees of Glasgow town council are drawing up a scheme for the immunisation of school children against diphtheria. The scheme will be voluntary, requiring the signed consent of parents, and its working will be undertaken by the public health and school medical staffs with the assistance of health visitors. A notice will be placed in each child welfare and school clinic giving details of the scheme, and information regarding the incidence of diphtheria and the value of immunisation will also be distributed to parents. The medical officer of health proposes that each child should be given two inoculations with a fortnight's interval between and inoculation will be carried out at the corporation clinics *in various parts of the city*.

REFUGEE WOMEN AS MIDWIVES

On the request of the midwives department of the Coördination Committee for Refugees the Greenock corporation has decided to allow six women refugees from Germany, Czecho-Slovakia or Austria to become pupil midwives at the Rankin Hospital. The convener of the public-health committee admitted that there was difficulty in obtaining the services of midwives at present, but he thought there were enough suitable women in this country without calling on foreign refugees. The medical officer of health said, however,

that the services of these women are urgently required, and indeed that the Rankin Hospital may have to close down unless something is done to relieve the situation. After the present batch of pupil midwives have completed training there are no more to come forward. In agreeing to give this permission to the refugee women the corporation decided to ask for a guarantee that they would not remain in the district and compete with nurses in Greenock after completing their training.

CAMPAIGN AGAINST RHEUMATISM

A resolution urging the Government to set up clinics for the treatment of rheumatic diseases throughout the country has been adopted by the insurance committee for the county of Lanarkshire and it is to be sent to the annual conference of the Scottish Association of Insurance Committees at St Andrews in September Lanarkshire is said to be suffering severely from a lack of provision for such treatment and even in Glasgow the facilities seem to be insufficient. Lanarkshire has the highest sickness-rate in Scotland, and the committee urges that one of the most effective ways of remedying this state of affairs would be the development of more efficient treatment both for those who are already incapacitated by rheumatism and for those in whom the disease can still be checked in the early stages.

(FROM AN OCCASIONAL CORRESPONDENT)

THE NEW CARNET DE SANTE

Monsieur Marc Rucart, the French Minister of Public Health, has recently sponsored the issue of a health passport of which great things are expected Hitherto, sporadic attempts to put systematically on paper the most important medical features of Frenchmen have been successful enough within their limited spheres and have pointed the way to a more comprehensive scheme on national lines Every French baby is now entitled to receive at birth, free of charge, a health passport in which are to be entered all the important medical events in his or her life as they occur, from vaccinations and inoculations to the operations of the dentist In a sense, this passport is to take the place of the more or less defunct family doctor As the patient enters the consulting-room of a specialist for the first time, it will not be a letter from the family doctor but this passport, presumably kept well up to date, which will provide those clues with which even the most perspicacious specialists cannot always dispense The identity of the owner of the passport is not betrayed on it by his name, being indicated only by a number This should be of use if the passport is lost Further, it provides for the preservation of professional secrecy. The passport should prove useful to the Army Medical Service, but inquisitorial employers in civil life are not entitled to see it. The first part of the passport will record information about heredity, operations, vaccinations, accidents, rate of growth and so on. In short, it will be the medical history of the holder and his or her parents The second part is intended to serve as a dental-history record The card is not compulsory, but parents and guardians are urged to endow every child with it, and to ensure that the necessary records are entered in it as promptly as possible. The reception given to this health passport by the French press has, on the whole, been favourable.

IRELAND

(FROM OUR OWN CORRESPONDENT)

THE LUNACY LAWS

A MOVEMENT for radical reform in the laws relating to lunacy has shown itself among the administrative authorities of the public mental hospitals in Ireland. The committee of the Grangegorman (Dublin) Mental Hospital—the largest and most important in Ireland—following the lead of the committee of the Sligo Mental Hospital, last week adopted a series of resolutions to be submitted to the Government, recommending several far-reaching reforms, and asking for the appointment of a commission of experts to study the matter

Among the reforms recommended is an alteration in the laws governing the admission of patients to the public mental hospitals. It is suggested that the present laws practically necessitate that prospective patients should be regarded either as criminals or as paupers in order to secure admission. The result is that relatives are deterred from putting patients under treatment until the disease is far advanced. To remedy this defect the reception and treatment of voluntary patients in the public hospitals should be legalised. At present voluntary patients can only be received in private institutions The committee also suggest the establishment of separate institutions for separate classes, for example, mental defectives, epileptics, recent cases of insanity and chronic cases. That the time is ripe for such reforms is beyond doubt, and it is a healthy sign that the committee of the mental hospitals recognise the fact.

SWEDEN

(FROM AN OCCASIONAL CORRESPONDENT)

POLIOMYELITIS IN TOWN AND COUNTRY

A FEW weeks ago Dr. Jönsson published a thesis on poliomyelitis, in which he deduced that the disease is just as frequent in urban as in rural communities Dr. Jönsson has started a controversy whose temperature has reached almost theological heights. Prof. C. A Kling, of Stockholm, has pointed out that the evidence in support of poliomyelitis as an eminently rural disease is wellnigh overwhelming In his study of the epidemic in Sweden in 1905, Wickman found that only about 12 per cent of all the cases occurred in towns. Leegaard came to approximately the same conclusion for Norway between 1904 and 1912 Studying the great Swedish epidemic of 1912–1913, Wernstedt found that the more urban the population, the lower was its morbidity. Prof. Kling himself has come to the same result from his studies of poliomyelitis in Rumania in 1927. A study of conditions in Finland, which Prof. Kling has not yet published, has yielded similar findings What the orthodox would consider as the Jönsson heresy deals with the behaviour of poliomyelitis in Sweden between 1921 and 1937, and it is suggested that he has gone astray in attaching too much importance to non-paralytic cases of the disease, in many of which the diagnosis may have been mistaken. Prof Kling, who is in charge of the state bacteriological laboratory in Stockholm, hopes soon to be in a position to issue a report on a prodigious work undertaken by his staff about the behaviour of poliomyelitis in Sweden between 1933 and 1938. To establish a comprehen-

ive epidemiological survey, some 8000 records have been sifted In attempting to extract valuable information from this enormous and amorphous mass of documentation, Prof Kling must be haunted by the dread of every thoughtful artist—shall I, in painting in all these trees, end by hiding the wood?

INDUSTRIAL DISEASES

In the course of only two or three generations the familiar agricultural timber growing Sweden has become industrialised to a remarkable degree A sign of the times is to be found in the Lennander lecture delivered this year by Dr Gerhard Rundberg, who chose modern industrial diseases as his subject Since 1929, one law after another has been passed in an attempt to protect the worker from the risks of his employment, and even now the legislative net has not succeeded in catching all the industrial fish Certain infectious conditions are now included within the ambit of industrial diseases, and the statistical returns for the year 1938 include sixty five cases of scarlet fever, and one case each of diphtheria, infantile paralysis and undulant fever, these qualified the sufferers for compensation under the new law The predominance of scarlet fever over various other infectious diseases is to be explained by the fact that it has recently run riot in Sweden Lead still claims some twenty five victims every year in spite of all precautions During the 7 years silicosis has been included among the industrial diseases qualifying for compensation it has claimed 143 victims, an average of little more than twenty cases a year There is approximately the same yearly average from poisoning with benzene and allied chemicals

To illustrate the suddenness with which new industrial diseases may arise, Dr Rundberg gave an account of a Swedish metallurgical firm which, at the end of 1938, received a small order from Germany for an iron compound of vanadium The order being small, and the work on it being considered as provisional, little was spent on precautions against poisoning But after only a day's work in contact with vanadic acid, several of the workmen developed severe bronchitis with profuse yellowish green expectoration, as well as general lassitude and irritation of the skin of the face and hands Naturally enough, the men refused to continue their work In cases such as this, it is fortunate that the good times at present prevalent in the industrial world encourage employers to incur expenses in the protection of their workmen against industrial risks

LETTERS TO THE EDITOR

HEREDITY OR ENVIRONMENT?

SIR,—Your leading article of two weeks ago headed Neurosis or Psychosis? contains the sentence "This school finds that in the causation of the neuroses and psychoses both heredity and environment play their part, . . " The common fallacy that heredity and environment can be treated as separate entities thus appears, no doubt unintentionally, to receive editorial sanction Luxenburger[1] has shown that binovular twins have only a small liability to concordant schizophrenia, but that the likelihood of monovular pairs agreeing is great With certain reservations and assumptions, we can deduce from his figures that the environment of the developing fœtus in the uterus is not an important factor, that the environment of postnatal life is also of little importance unless a particular hereditary constitution is present, and that the postnatal environment is of very great importance when this susceptible type of constitution is present Schizophrenia is therefore like the other common diseases It is meaningless except under special circumstances as Hogben[2] has pointed out, to discuss whether heredity or environment is the more important, because the answer depends on our personal philosophical outlook Given a good or perfect environment, heredity is unimportant From the opposite point of view, in a world where good and bad environments are the rule heredity does in fact determine the incidence of schizophrenia, as well as most other non infectious diseases

Might I follow this chain of thought further and give some other examples of the interaction of heredity and environment? If a suboptimal amount of vitamin C is present in the diet of guineapigs, some animals will develop scurvy and others won't By selective breeding it is theoretically possible to isolate strains with varying resistance to C deficiency Under these conditions, an intelligent, medically minded guineapig knowing nothing of other types of diet, might be excused for thinking that scurvy was a hereditary disease and that his human masters were justified in following a eugenic policy to eradicate it Another example can be taken from stock farming Our cattle are doing well, but we decide to try a new regime Some of the animals do well on it, some badly We are faced with two alternatives Either we breed from the animals who do well and attempt to establish a race which suits the new conditions Or we decide to go back to the old regime and not venture on a course of selective breeding the consequences of which might in the long run be disastrous

Parallels to the attitude of mind of our medical guineapig are easy to find in the history of human medicine The connexion between environment and disease is only obvious when two populations living under different conditions are studied together When the environment is more or less standardised, heredity or diathesis must inevitably appear as the factor responsible for disease, even as recently as the last two decades, the ideas of the scorbutic diathesis and rickety diathesis have been revived in out of the way communities In the past fifty years a revolution in our habits of life has occurred Some of the changes seem inevitable and irreversible Other changes, especially dietetic ones, are more under our control It is unfortunate that at this biologically interesting juncture in the history of the human race prevailing medical fashion is going back to the dark ages and again ascribing ill health to diathesis and heredity The history of medicine shows that these conceptions, however true are sterile They have done little or nothing for the prevention and treatment of disease and it is easy to find examples of how they have actively retarded progress Today ideas such as the hyperchlorhydric diathesis or the highly strung temperament relegate to the background the study of the effects of diet It would be ludicrous, if the results were not so sad, that in all the experimental dietetic work which has been carried out, there have been no parallel X ray and endoscopical observations on the intestines

1 Luxenburger H *Z indukt Abstamm u Vererb Lehre* 1932, 61, 323
2 Hogben L Nature and Nurture 1933

I conclude by re-emphasising that biological theory and twin research (as carried out on the totalitarian scale in Germany) show the universality of this interaction between heredity and environment in disease. And further that medical history warns us that the constitutional factor in disease is difficult to understand and still harder to treat The environmental factor, on the other hand, may be surprisingly easy to control when it is simplified to essentials.

I am, Sir, yours faithfully,

Oxford, Aug 19 DENYS JENNINGS.

NEUROSIS OR PSYCHOSIS?

SIR,—Your leading article under this heading stimulates comment of many kinds, but I shall confine myself at present to pointing out the practical implication of the "quantitative" view of the difference between "neuroses" and psychoses It is simply this, that since neuroses are but mild psychoses (sic) and since psychotherapy is of little use in the latter, so it is of minor importance also in the former. It would be a great pity if the influence of this doubtful (and I think, unscientific) view were to discourage the use of the more recondite forms of psychological treatment by those medical men who have both the aptitude and the necessary type of training.

This is all the more important since it was recently evident at the Mental Hygiene Conference, convened by the National Council for Mental Hygiene, that lay people feel not only that there is a need for this kind of treatment but that the medical profession is failing to supply it It was I believe largely with this factor in mind, and with a consciousness of the justice of the criticism, that a committee of the B.M A. recently recommended the recognition of lay psychotherapists This dubious experiment may yet be forced upon us While there is yet time, it is essential that those who can influence medical opinion with regard to the nature of neurotic illness should be willing to admit what is well established—that there is a technique of psychotherapy of a sort which does require special gifts, special experience and (except in a few with a special share of the divine afflatus) a prolonged course of training This needs stressing if we are not to lose the ground which has been won, often by members of the profession whose work has been grudged recognition by its own high priests We are told that "there is nothing in psychotherapy that any doctor with the right personal qualities and a few fundamental principles to guide him cannot learn for himself" Substitute "surgery" for "psychotherapy" and the quality of this corollary of the quantitative theory becomes evident

I am, Sir, yours faithfully,

R. D GILLESPIE

Chester Terrace, N W 1, Aug 22

"DORMANT" LEAD POISONING

SIR,—I should like whole-heartedly to support the remarks contained in the annotation in your issue of Aug 19 under this heading It is indeed time that some of the myths associated with lead poisoning were cleared up In the past there has been a tendency to accept these cases far too uncritically, and in more recent years the "mobilisation of dormant lead" is frequently called in to explain symptoms without sufficient evidence. It is obvious that anæmia colic and constipation are common symptoms, and in most cases there is no history of previous lead absorption If, however, such a history is forthcoming, there is a dangerous tendency to attribute the symptoms to the lead exposure, irrespective of when it occurred or of what degree it reached. It would be interesting to know on what grounds Dr. Gordon Ward, during the war years, ascribed the symptoms in his cases to lead that had been absorbed many years previously.

Over fifteen years ago Aub and his collaborators showed that lead could be mobilised from the bones; and, in fact, most clinicians with a reasonably wide experience of these cases will have at some time precipitated symptoms in a recent case of plumbism by too vigorous "de-leading." But this is a totally different question from the mobilisation of lead after a period of years As you point out in your annotation, lead soon passes from the trabeculæ, where it is comparatively easily influenced; and having done so, I know of no reliable evidence, either clinical or biochemical, to suggest that it can again easily be brought into the circulation in sufficient quantity to produce severe symptoms. This experience is, I know, similar to that of two leading American industrial physicians who have special opportunities of meeting these cases

May I enter a plea for a more critical attitude in these cases? It is easy and tempting to accept a seemingly plausible explanation for a puzzling case, but this is one which I feel must be resisted in the absence of adequate proof.

I am, Sir, yours faithfully,

RONALD E LANE.

Salford Royal Hospital, Salford, Aug 20

FIRST-AID FOR EYE INJURIES

SIR,—I was interested in your report on Aug. 19 of the discussion on ophthalmic services to the civilian population in national emergency, which formed a part of the programme of the British Medical Association's section of ophthalmology, recently held in Aberdeen

It seems from this report that opinions were equally divided for and against the use of cocaine—in favour of it as a local anæsthetic affording relief to persons whose eyes are injured by mustard gas and against it because of its damaging effect on the corneal epithelium I was not present at the meeting and so I do not know if the advantages of Pantocain as a local anæsthetic were mentioned Some years ago I abandoned the use of cocaine in all ophthalmic work and have since preferred pantocain in ½ or 1 per cent solutions It has no deleterious effect on the corneal epithelium, the regeneration of which is not retarded or interfered with in cases of abrasion and ulceration, the pupil is not dilated, the intra-ocular pressure is not raised and there are no general toxic effects from the use of this drug as a surface anæsthetic For 40 seconds after instillation a burning sensation is felt and a transitory blepharospasm is evident The hyperæmia of the conjunctiva induced by pantocain is abolished by a drop of adrenaline if surgical intervention is necessary

It seems to me that pantocain would be of considerable service in the first-aid treatment of gas casualties in relieving pain and thereby calming those afflicted, and that it could be used without danger by lay persons in first-aid posts and mobile units Those injured by mustard-gas vapour would thus be made relatively comfortable and be able to open their eyes, within their gas respirators, sufficiently to walk to a hospital or ambulance-transport post.

I am, Sir, yours faithfully,

Harley Street, W 1, Aug. 23. H. B. STALLARD.

MEDICAL STUDENTS IN WAR-TIME

SIR,—As a medical student, may I be allowed to comment on one important omission from the otherwise careful arrangements for our allocations to various hospitals for war services? It is this—that it seems to have been forgotten that in asking students to carry out such duties they are being placed in the unhappy position of appearing invidiously unique, for in the event of war what other fellows of our age will be about in England? If we exclude conscientious objectors, then it may be said that nearly all our contemporaries in all their various employments will have joined up, and we shall surely be pretty well the only ones not in the fighting services

We have been told and know now that it is our duty to remain behind, to get qualified and then to serve our country, in the services or at home, making use of our professional abilities Thus, it is not for us to follow the many medical students of 1914, who eagerly joined the fighting forces, and who, by their tragic loss, caused the shortage of medical men in subsequent years of the war

But the layman does not appreciate all this, and it is shameful that we should be thought "lucky to be out of it" This implication of "justifiable avoidance" of more dangerous belligerent duties abroad, with the risk of verbal 'white feathers" being thrown at us, is, to say the least, distasteful

I suggest that some insignia, equivalent to the T.A and A R P badges, which could be well understood should be arranged for us Many explanations would then be unnecessary, and none would doubt our honour

I am, Sir, yours faithfully,

L D DE LAUNAY,
Sgt No 7 Coy Medical Unit U L O T C, O G R
The Medical School King's College Hospital,
S F 5 Aug 26

PHYSICAL METHODS IN RHEUMATIC DISEASE

SIR,—It is to be regretted that Dr. H J Taylor's letter in your issue of Aug 19 in no way answers my letter in your issue of the 12th May I again emphasise that a physicist of repute, Dr Judd Lewis, has clearly demonstrated the marked difference in the spectrograms of the titanium alloy arc and the tungsten arc It is known that the addition of iron or tungsten to the core of a carbon makes a vast difference to the output of ultraviolet irradiation Similarly the addition of a small quantity of titanium to tungsten makes a very considerable difference to the output of the total radiant energy—including ultraviolet—from the arc

Surely it is unscientific and wrong to condemn the titanium alloy arc and also low intensity treatment when clinical tests have not been carried out

I am, Sir, yours faithfully,

W ANNANDALE TROUP

Wimpole Street, W 1 Aug 19

PUBLIC-SCHOOL AND SECONDARY-SCHOOL BOYS

SIR,—I read with great interest Dr Bathurst Norman's valuable article in your issue of Aug 19 May I, however, as a matter of record be permitted to recall the fact that the relation of stem length (sitting height) to body weight, the method of measuring stem length and the precautions necessary to avoid errors into which some observers had fallen, for which he quotes Dreyer and Hanson (1920) were put forward by me in a communication on the growth of the body in man, published in the *Proceedings of the Royal Society* (1915, 89, 157) The reference to my paper was given by Dreyer and Hanson in their preliminary article (*Lancet*, 1919, 2, 227), but, by an unlucky oversight, it was not repeated among the references given in their book "The Assessment of Physical Fitness," and it therefore tends to be overlooked Dreyer and Hanson's important studies supported my conclusion that the normal weight of the body is related to the stem length But the much more extensive data, which they were able to collect, with the aid of the Medical Research Council, led them to make some small numerical change in my formula Had my lamented friend, the late Prof Georges Dreyer, been alive, he would have been the first to acknowledge the assistance he obtained from my earlier inquiry

I have recently entrusted the individual data and the calculations concerned therewith to Dr E P Poulton, of Guy's Hospital, since application made by him to the Royal Society has disclosed the fact that my original manuscript and some valuable tables, which latter were not printed for reasons of economy, are no longer in their possession

I am, Sir, yours faithfully,

E W AINLEY WALKER.

University College, Oxford, Aug 28

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUG 19, 1939

Notifications.—The following cases of infectious disease were notified during the week Smallpox, 0, scarlet fever, 1200, diphtheria, 742, enteric fever, 48 (53 "expected"); pneumonia (primary or influenzal), 350, puerperal pyrexia, 175, cerebro-spinal fever, 17, poliomyelitis, 25, polio-encephalitis, 3, encephalitis lethargica, 1, dysentery, 39, ophthalmia neonatorum, 100 No case of cholera, plague, or typhus fever was notified during the week

The number of cases in the Infectious Hospitals of the London County Council on Aug 26 was 2303 which included Scarlet fever 503 diphtheria, 480 (carriers, 13), measles, 18 whooping-cough 552, puerperal fever, 21 mothers (plus 10 babies) encephalitis lethargica, 304, poliomyelitis 21 At St Margaret's Hospital there were 18 babies (plus 10 mothers) with ophthalmia neonatorum

Deaths.—In 120 great towns, including London, there was no death from smallpox, 4 (0) from enteric fever, 2 (0) from measles, 1 (0) from scarlet fever, 8 (2) from whooping-cough, 14 (1) from diphtheria, 43 (11) from diarrhœa and enteritis under two years and 10 (1) from influenza The figures in parentheses are those for London itself

Hornsey Southampton Stoke-on Trent and Cardiff each reported a death from typhoid Fatal cases of diphtheria were scattered over ten great towns Sunderland reporting 3 Chester and Liverpool each 2 Hull and Birmingham each had 3 deaths from diarrhœa.

The number of stillbirths notified during the week was 215 (corresponding to a rate of 37 per 1000 total births) including 45 in London

POSTGRADUATE COURSE IN VENEREAL DISEASES.—A course of instruction in modern methods in the diagnosis and treatment of venereal diseases will be given by Lieut-Colonel L S Burks during October, November and December at the London County Council (Whitechapel) Clinic Turner Street, E 1 Lectures will be given on Mondays and Thursdays at 2.30 P.M., beginning on Oct 2, and on Wednesdays at 2 P.M there will be case demonstrations Further information was given in the advertisement columns of our last issue

PARLIAMENTARY INTELLIGENCE

ON THE FLOOR OF THE HOUSE

BY MEDICUS, M P.

THE House of Commons has held two special sessions to deal with the danger of war between Germany and Poland—a danger which would automatically involve Great Britain and France because of our treaties with Poland if war broke out. The week between the meetings has been one of what amounts to a general mobilisation of the armed forces and of the civil defence forces. The news of the Soviet-German pact burst like a bombshell on the country and on the world, but left the nerves of the House and of the country undisturbed. This even tension of nerves marked both the meeting of the House of Commons last week and the meeting this week. Last week, with no serious criticism, the bill to give the Government power to make any regulations necessary for the Defence of the Realm passed both Houses of Parliament in one day. This week *the Prime Minister's statement on the situation* was received with purely formal criticism by the leaders of the Labour and Liberal oppositions But the leader of Labour urged the Government to set about the evacuation of children and the priority classes from the towns while there was yet a lull

The Prime Minister's speech of last week—on Aug 24—has already become a historic document It was debated by some of the first-class brains in the House, but not all the speeches were first class either in matter or in presentation and the debate towards the end was rather ragged. The significance of the debate was in the division list—427 members of all parties voted to give the Government emergency powers and 4 members voted against it. This balance of members very fairly expresses the feeling of the House and of the country to be finished with the business. This time there must be no compromises, no more Munich settlements Mothers with sore hearts waiting outside schools while their children are instructed in evacuation methods say it Workmen building homes or in their workshops say it . . Men at their desks . . Doctors and nurses in hospitals . .

Let us trust that the resolution of the Government will be equally firm. The gage of battle now is no *Czecho-Slovakia but the honour and physical security* of Great Britain and all it stands for of fair-minded freedom in life, in thought and in work So felt the House of Commons on Tuesday, Aug. 29, 1939 The House is to reassemble in a week's time unless emergency before that calls it together again.

MEMORANDA ON CASUALTY TREATMENT

THE Director-General of Emergency Medical Services has prepared a series of memoranda for the information of medical officers of health, group officers and others responsible for civilian casualty organisation One memo gives some general and more detailed advice on early treatment at first-aid posts The first-aid worker is warned against attempting more than his training has fitted him for, and is urged to cultivate common sense rather than overconfidence. The technique recommended generally follows that of the manuals

Another memo deals with the provision of tetanus and gas-gangrene antitoxin. The former is being stored in fifty centres so that it will be immediately available when required Some authorities have advocated a prophylactic dose much larger than that used so successfully in the last war; the dose advised here is 2 c.cm. of the liquid serum provided, which will represent about 2600 international units The serum will be supplied in multiple-dose bottles holding 30 or 60 c.cm, which can be used for a week after the bottle has been opened. For treatment tetanus antitoxin will be supplied in sealed ampoules each containing a single dose of 24,000 international units in some 8 c.cm The arrangements made for the supply of gas-gangrene antitoxin allow for the administration of welch, vibrion-septique or œdematiens antitoxins either separately or combined. Little is known about the dosage of these sera, and that recommended may have to be modified in the light of experience. For prophylaxis the provisional dose advised is 3000 units of welch, 1500 of vibrion septique and 1000 of œdematiens For treatment a combined injection containing 7500 units of welch, 3750 of vibrion septique and 2500 of œdematiens is recommended, and separate antitoxins will be available for intensive therapy where the causal organism has been identified Supplies of these sera will be kept in London, Newcastle, Leeds, Manchester and/or Liverpool, Nottingham, Birmingham, Cambridge, Oxford, Bristol and Cardiff.

It is proposed to provide special centres where certain types of disability can be collected and treated by a specialist staff In the early stages of a war, however, while the switch-over from the central organisation of peace-time to a decentralised organisation is taking place, systematic sorting of cases is likely to be impracticable No attempt will therefore be made to segregate cases in special institutions during the first few days, in this period advance base hospitals will have to be prepared to treat any type of injury. The need for segregation in a special institution is perhaps most urgent in those suffering from neuroses uncomplicated by injury and an effort will be made to provide special treatment from the outset for such patients who are not fit to go home. As regards first-aid, in simply frightened and emotional cases reassurance combined with an appeal to personal and patriotic pride and a large dose of bromide is expected to be sufficient. When confusion, excitement, loss of memory or disorientation are the chief symptoms, rest and warmth, hot drinks with plenty of sugar, and either bromide or phenobarbital or, where there is much restlessness, an injection of morphia or sodium phenobarbitone and hyoscine are advised. When hysterical symptoms predominate medical officers of first-aid posts are urged to attempt to remove them at once by suggestion The main aim in all but the most severe neurotic cases will, however, be to send the patient home as soon as possible.

". . It has come to be my feeling that many of the wound infections which we see are not due to the organisms which get into the wound at the time of the injury, but to bacteria which are introduced during efforts at first aid Copious hemorrhage, anxious relatives and friends, insistent demands for immediate treatment, often lead the physician or first-aid man to do things which cause irreparable damage"—MICHAEL L MASON, *Surg. Gynec Obstet.* August, 1939, p. 113

OBITUARY

LEONARD WILLIAMS

M D CLASG

THE genus homo, said Leonard Williams in his Cavendish lecture in 1927, inherits from his simian ancestors a certain playful devilry of spirit Certainly some such spirit permeated his own life and was responsible for the pungency and deliberate challenge of his writings and for his occasional conflicts with accepted orders The general reader will remember him chiefly for his terse and much quoted comments on modern habits of diet and hygiene and for his little books on minor maladies He died in London on Aug 20 at the age of 77

Leonard Llewelyn Bulkeley Williams was by birth, as by name, physiognomy and temperament, a Welshman He was the youngest son of David Williams, M P , of Dendraeth Castle, Merioneth shire, and was educated at Marlborough, *Glasgow University* and St Thomas's Hospital He qualified in 1886, and after studying in Germany and France went into practice at Sidmouth About 1900 he migrated to London as a consultant physician, and there he *interested himself in balneology*, editing the *Journal of Balneology and Climatology*, and began to write extensively on the endocrine, dietetic and habitual factors that influence general health He proved himself a skilful writer of entertaining prose with clear cut and often individual views He supported the Arbuthnot Lane school in blaming habitual constipation for many of the 'civilised' diseases and was an enthusiastic advocate of the natural rather than the commercially prepared foods Premature senescence he attributed largely to gluttony and crude cookery ("cookery is too often penury masquerading as magnificence "), and for a long life he prescribed hard work, moderation in diet punctuated by fasting, and plenty of fresh air *Obesity* was his bête noire and he particularly condemned pressing meat extracts and the like in acute illness In comparison with the ordinary British invalid,' he said "the forcibly fed Strasbourg goose is an ascetic

In 1915 Dr Leonard Williams took over the editorship of the *Medical Press and Circular* when Walsh retired, and during the war years he contributed a weekly paragraph always witty and often disrespectful, over the apt pseudonym 'Sanpis' He was physician to the French Hospital, the Metropolitan Hospital and the Miller Hospital Greenwich Since the war, apart from a multitude of short articles and papers, lectures and addresses – for he was as facile a speaker as a writer – he produced a succession of editions of his 'Minor Maladies and Wrote 'The Science and Art of Living Middle Age and Old Age' 'Obesity, and 'Growing Old Gracefully' Though his views were not always generally accepted, he practised them himself with as much vigour as he preached them to his patients

A friend of forty years standing writes "Leonard Williams was a great admirer of France, and one of the most useful things he accomplished was a better mutual understanding between French and English medical men A connoisseur of beautiful things, a witty conversationalist, genial among friends, with an appearance which grew increasingly striking with the years—it may be wondered why with all these gifts he did not achieve a still higher position in the profession I think the main reason was that he allowed his enthusiasms to outstrip his judgment Once seized with an idea he was apt to carry it to extremes This was particularly obvious in his views on diet Moreover he had a decided taste for controversy and was a bonny fighter Now he is at peace with all the world, and his friends will forget his faults of judgment, remembering with affection his charming companionship "

WILLIAM CARSON

M D BELF , M R C O G

Dr William Carson died on Aug 13in his fortieth year after a long and painful illness He was a young man of outstanding ability and great promise After an early struggle which would have daunted many a lesser spirit, he graduated at Queen's University, Belfast, with honours in 1922 After serving as a resident in the Maternity Hospital, Belfast, he held a similar appointment in the Soho Square Hospital for Women in London Later he was elected to the *staff of the Samaritan Hospital, Belfast*, and the Belfast Union Infirmary

His prime characteristics were his dynamic enthusiasm and an unflagging fund of good humour He was a versatile and resourceful surgeon, with a passion for accurate technique and a deep regard for the anatomical and physiological truths As a teacher his talents were obvious He was friendly and approachable and had a sympathetic appreciation of the student's difficulties

Carson possessed an original and inventive mind, and for years he was fascinated by the problems of carcinogenesis The specific effects of abortus infection on animal chorionic tissue suggested to him the possibility that they might be of use in destroying malignant tissues in man While studying the effects of these organisms on patients with cancer, he found his work hampered by the solid immunity which developed in all cases He decided that a normal control was essential and, in spite of the protests of his colleagues, he made himself the subject of further experiments These resulted in a violent and devastating porcine abortus septicæmia which raged for many weeks and *permanently impaired his health* He showed great fortitude and cheerfulness in the face of physical suffering

---

Since 1936 London hospitals have joined to hold combined collections on three days of the year The general hospitals made their collection in inner and outer London during May On Tuesday Oct 10, the special hospitals will hold their flag day Those who wish to help should get in touch with the London Hospitals Street Collections Central Committee, 36 Kingsway, London, W C 2

UNIVERSITY OF LONDON —If a state of national emergency is declared no examinations will be held at the university till further notice

Notes, Comments and Abstracts

LIMITATION OF NUMBER OF PRACTICES

THE *enterprising young man who builds up practices*, one after the other, in order to sell them and move on is criticised by a correspondent in *Concours Médical* of June 4. He tells the story of a practitioner who set up in a district where hitherto there had been room for only one doctor, and in six years secured a large proportion of the patients. He then sold his practice to the highest bidder, settled down 40 kilometres away, and repeated the process. The next step was to settle in a large town as a supervisor of his fellow-practitioners working under the national health-insurance scheme. Being now a capitalist, through the ruin of two of his colleagues, he was in a position to live happily ever after, his income from investments supplemented by his government salary. The *Concours Médical* correspondent thinks such behaviour could be frustrated if a limit were put on the number of practices Already, it appears, French notaries must step into each others' shoes instead of making a new pair This system, it is suggested, would also be advantageous for the practitioner's widow; for at present she is liable to find the sale value of her husband's practice dwindling rapidly within a few days of his death, because a "squatter" has been free to jump the claim.

FOR THE AMATEUR DOCTOR

WHETHER the layman is in fact more helped than alarmed by his medical reading is a moot point. As long ago as 1907 the faculty of the Harvard medical school formed the opinion that "health-consciousness" had reached a stage which demanded that something should be done to satisfy public curiosity. A course of free and authoritative lectures on Sunday afternoons was inaugurated and these have since continued, almost without interruption Their aim has been "to clarify, explain and interpret recent developments in various fields of medicine and research, to warn of unsuspected dangers, and to stress the necessity of seeking sources of skilled advice," as apposed to procrastination or quackery. The volume before us ("Health at Fifty," edited by William H. Robey. London: Humphrey Milford, Oxford University Press. 1939. Pp 299. 12*s* 6*d*) comprises a dozen of the more recent lectures, dealing with heart disease, high and low blood-pressure, underweight and overweight, the cancer problem, rheumatism, menstrual disorders, vitamins, care of the eyes, hormones, the family medicine-chest, social stress and mental health, and old age. The manner of presentation is honest and accurate. There might be less anxiety about the activities of the amateur doctor if one could be sure that his information was derived from sources as reliable as this.

Vacancies

St Paul's Hosp. for Urological and Skin Diseases, Endell St, W C 2—Hon. Anæsthetist.
Albert Dock Hosp, Alnwick Road, E.16—Second Res M O, at rate of £110
Chester Royal Infirmary.—H S to ear, nose, and throat, and gynæcological depts, £150
Princess Louise Kensington Hosp. for Women, St Quintin Avenue, N. Kensington, W.10.—H P. and H S, each at rate of £120
Hospital for Sick Children, Gt Ormond St, W C 1—H P. and H S, each at rate of £50
Bolingbroke Hospital, Wandsworth Common, S W.11—R S O, £200 Also H P. and Cas O, each at rate of £120.
Wrexham and East Denbighshire War Memorial Hospital—R H S, at rate of £150.
Lancaster Royal Infirmary—2nd H S, at rate of £175
Mansfield and District General Hosp—H S, at rate of £150
Northampton General Hosp—H.S, at rate of £150.
Nelson Hosp, Merton, S W.20—Res H.S, at rate of £150
Salvation Army Mothers' Hosp, Lower Clapton Road, E 5—Jun Res. M O, at rate of £80.
Tottenham Borough.—Temporary Asst M O.H. (A.R P.), £550.
Manchester Withington Hosp—Asst to Res Obstet. Officer, at rate of £250. Also Res. Asst M O, at rate of £200
East End Maternity Hosp, 396 Commercial Road, E 1—R.M.O, at rate of £150

Medical Diary

Sept 4 to Sept 9

UNIVERSITY OF GLASGOW
TUESDAY—4 30 P M (Tennent Memorial Building, 38, Church Street) Prof A J Ballantyne Problems of Vision in Aviation

EDINBURGH ROYAL INFIRMARY
THURSDAY—5 P M, Dr James Slater Physical Education in the University of Edinburgh (Honyman Gillespie lecture)

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W 1
MONDAY to SATURDAY WEST END HOSPITAL FOR NERVOUS DISEASES, Regent's Park, Mon and Fri, 8 P M, lecture-demonstrations in neurological surgery for F R C S (final) candidates—BROMPTON HOSPITAL, S W 3, Tues and Wed, 5 15 P M, course in chest diseases, for M R C P candidates MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W 1, *Mon, Wed, and Fri, 5 15 P M, course in physiology for primary F.R C S candidates*—ROYAL CHEST HOSPITAL, City Road, E C 1, 8 P M, lecture-demonstrations in chest and heart diseases (Open to non-members)—ST MARY'S HOSPITAL, Paddington, W 2, Tues and Thurs, 8 P M, clinical and pathological M R C P course

Births, Marriages and Deaths

BIRTHS

BALL.—On Aug 24, at Barton-on-Sea, the wife of Dr Harold C J Ball—a daughter
BEALL.—On Aug 26, at Chatham, Ontario, the wife of Dr Geoffrey Beall—a son
CARNEGIE BROWN.—On Aug 21, at Wool, Dorset, the wife of Dr G Carnegie Brown—a son
CHEVERTON.—On Aug 23, at Belize, British Honduras, the wife of Dr L Cheverton—a daughter
COFFEY.—On Aug 18, at Muswell Hill, N 10, the wife of Dr W. J Coffey—a daughter
GOOD.—On Aug 25, the wife of Dr Michael S Good, of Aylesbury—a son
HERTZOG.—On Aug 21, at Ramsey, Huntingdon, the wife of Dr Willem Hertzog—a son
JACKSON.—On Aug 28, to Dr Margaret Jackson (nee Hadley), the wife of Dr L N Jackson, of Crediton, Devon—a son
KING LEWIS.—On Aug 25, at Bromyard, Herefordshire, the wife of Dr P C King Lewis—twins, a son and a daughter
LAURENT.—On Aug 23, at Putney, the wife of Dr A M P Laurent—a son
REID.—On Aug. 22, the wife of Dr A. Reid, of Clare, Suffolk—a son
WILLIAMS.—On Aug 23, at Southsea, the wife of Surgeon Commander J V. Williams, R N.—a son

MARRIAGES

ROWORTH—READE.—On Aug 21, at Woodham Church, Charles Guy Roworth, M D., to Christine Sylvia Reade

DEATHS

COCKBURN SMITH.—On Aug 22, at Newton Abbot, George Cockburn Smith, M D Brussels M R C S, aged 92
FLEMMING.—On Aug 25, Arthur Launcelot Flemming, M D Brist, of Clifton, Bristol
HAYES.—On Aug 26, at Carr Bridge, James Hayes, M R C S, of Tunbridge Wells, aged 83
KOCH.—On Aug 28, Wilfred Vincent Miller Koch, M D. Edin., of Bath, late of Hong-Kong
STAFFORD.—On Aug 18, at Nottingham, William Stafford, M B Glasg
THOMPSON.—On Aug 24, at Paignton, John Thompson, F R C S.

Appointments

WRIGHT, FRANCES T, M B Manc, assistant medical officer at the outpatient department of the Royal Manchester Children's Hospital

Medical News

University of Cambridge

Dr. Peter Kerley has been appointed an examiner for the diploma of medical radiology and electrology (part II) in place of Dr. Russell Reynolds, who has resigned

Titles of degrees were conferred on the following members of Girton and Newnham Colleges during July:

A. G Gardham, M.B; W. F. Holman, M B, B Chir; R. M Howitt, M.B., B Chir; A M Lewis, M.B., B Chir., M. Savory, M.B, B Chir.; and M J Scott, M B., B Chir.

ADDRESSES AND ORIGINAL ARTICLES

ACUTE RHEUMATIC CARDITIS*

BY W T RITCHIE, O B E, M D Edin, F R C P E

PROFESSOR EMERITUS OF MEDICINE AND OF CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH

THE most frequent, and from the economic and social aspects the most important, form of myocarditis is unquestionably that due to rheumatism Other infective diseases have been eradicated from our land or are being brought under control, but rheumatic fever is still a prevalent scourge, rivalling if not surpassing tuberculosis as a cause of sickness and death A recent inquiry revealed that 1 in 8 of all medical inpatients in the principal hospitals of Edinburgh was affected with rheumatic heart disease, and that 52 8 per cent of all cases of heart disease in our Royal Infirmary were of rheumatic origin

The number of problems concerning rheumatism that still await solution is untold Its causation has not yet been determined, its relation to environmental factors, its infectivity and allergic nature are still uncertain (Hench et al 1938) We do not know why one child and not another, whether poor or rich, town dweller or country bred, falls a victim to rheumatic fever and is in imminent danger of becoming a cardiac cripple We have but a fragmentary knowledge of the end results of rheumatic heart disease when the circulation is failing On these matters I shall not dwell, but, although I may be thought "to carrie owles to Athens," I shall present some observations on acute rheumatic carditis

During a period of sixteen and a half years ending last autumn there were 268 cases of rheumatic fever, 127 males and 141 females, under my care in hospital Of these 43 per cent (51 males, 66 females) were between the ages of eleven and twenty, 65 per cent (75 males, 98 females) were between eleven and thirty The oldest was a woman aged sixty four, the youngest a girl aged six

Incidence

Of the 170 patients† observed in 1922–34 52 per cent were admitted during a first attack of rheumatic fever, 48 per cent during an exacerbation or recurrence, 6 per cent had previously suffered from chorea, and 47 per cent gave a history of existing or recently antecedent infection of the upper respiratory tract—e g, tonsillitis, pharyngitis, bronchitis, and sinusitis—or of aural sepsis In 2 cases acute appendicitis played the initiatory part usually taken by septic tonsils in the tragedy of rheumatic carditis Of these 170 cases there was acute polyarthritis in 157 (87 per cent) and carditis in 95 (53 per cent) In 47 1 per cent of the carditis cases the damage to the heart began during a first attack of rheumatic fever, in 47 1 per cent during a second attack, and in 3 8 per cent during a third attack Thus in 90 5 per cent of the carditis cases the heart became damaged during either a first or a second attack of rheumatic fever, and most of those thus affected were between the ages of eleven and twenty The risk of carditis lessens as the individual grows older Endocarditis, recorded in 89 cases (49 6 per cent), was considered to be "primary," not an exacerbation or recurrence, in 41 (22 9 per cent) Clinically this affected the mitral valve alone in 82 6 per cent, the mitral and aortic valves in 16 5 per cent, and the aortic valve alone in 0 9 per cent Pericarditis was observed in 35 cases (19 5 per cent), of which presented evidence of endocarditis also.

Diagnosis

Rheumatic carditis is in many respects analogous to tuberculosis The disease may be as quickly fatal as is miliary tuberculosis, or it may be a chronic process in which inflammatory fibrous tissue impairs the mechanical efficiency of the affected organ. The recognition of the beginning of both diseases is beset with difficulties That of carditis is often a mere supposition, because it usually begins insidiously during an attack of apparently uncomplicated rheumatic fever and develops gradually into a subacute or chronic process Many months, even years often elapse before the carditis is first recognised in the form of mitral stenosis or chronic myocardial failure

While the carditis is still in an early phase of development, cardiac enlargement can seldom be detected even by radiography, but the myocardial damage can sometimes be revealed by electrocardiographic abnormalities (Shookhoff and Taran 1931) similar to those arising during the course of other infective diseases, notably diphtheria and Chagas' disease (Chagas and Villela 1922, Chagas 1935). In a personal study of 100 cases of rheumatic fever 20 yielded normal electrocardiograms, auriculoventricular conduction time was longer than 0 19 sec in 37, and branch block or partial auriculoventricular block was found in 11 These changes usually disappear during convalescence (Parkinson, Gosse, and Gunson 1919–20) but may persist if there are obvious clinical signs of active carditis Unless obviously due to digitalis (Thomson 1934), conduction defects in rheumatic fever are usually considered to be indications of non specific inflammatory processes and vascular lesions in and around the conducting system of the heart (Walter 1938) Since the defect may be abolished by atropine (Bruenn 1937) it may also be due in part to an increase of vagal tone, this being probably a result of over activity of vagal nerve endings in the heart (Keith 1938) The deflexion T was inverted, diphasic, or otherwise abnormal in 9 cases Serial records by standard limb leads are useful in showing when abnormalities of T begin and whether they pass away Chest leads both apical and sternal, were used in 10 cases of rheumatic carditis, 8 being mild, 2 severe, 2 disclosed an abnormality of T which was not shown by the standard limb leads Right axis deviation was found in 13 and left axis deviation in 12, both are more frequent in recurrent attacks than in a first attack of rheumatic fever Ventricular extra systoles were recorded in 6 cases and auricular fibrillation in 5 Interference dissociation (Bain 1939) was never recorded In rheumatic fever without apparent carditis electrocardiograms, especially daily records by chest leads, afford a delicate means of revealing early damage to the myocardium, but they are often normal although the clinical evidence of carditis is beyond doubt

In a second, less frequent group of cases the carditis begins more acutely, the fever persists perhaps for several weeks, the heart's rate remains too fast even although the fever has subsided, endocardial murmurs

* The St Cyres lecture for 1939 delivered on June 8
† I have to thank Dr F H Vann for an analysis of these cases

become audible, and the sedimentation-rate remains high. Electrocardiograms are not needed for diagnosis; they are more often abnormal but may present no significant alterations a fortnight before an acute case ends fatally. If the patient survives, the inflammatory process in the heart ultimately undergoes fibrosis but, like a tuberculous lesion in the lung, it seldom heals, it merely becomes quiescent and is repeatedly liable to exacerbation. Thus, in the course of years there may be many cycles of activity alternating with quiescent phases, each of which may last for years.

A third, and smaller, group comprises the monocyclic cases in which the disease begins acutely, continues for days, weeks, or months, and usually ends fatally. It sometimes pursues a fulminant and speedily fatal course The most striking example is that rare and mysterious condition, rheumatic hyperpyrexia. In 2 instances this arose during a first attack of rheumatic fever and in 2 during a recurrence, the temperatures rising to 106 7° F. on the fifteenth day, 108° F. on the sixteenth day, 108 8° F. on the seventh day, and 109° F on the sixth day respectively. Neither the antecedent history nor the early features of the illness in these 4 cases gave any premonition of impending death Another virulent and fatal form of rheumatic carditis, fortunately rare, resembles acute septicæmia with a purpuric eruption, to which Libman (1923) directed attention This eruption is to be distinguished from that in subacute bacterial endocarditis and from a scorbutic eruption in chronic congestive heart-failure.

Of the many conditions for which acute rheumatic carditis may be mistaken the commonest is the febrile polyarthritic form of gonococcal arthritis, in which the complement-deviation test is, in my experience, always negative. Repeatedly negative blood-cultures and the absence of splenic enlargement and of Osler's nodes are foremost signs that help us to exclude subacute bacterial endocarditis. Acute staphylococcal osteomyelitis and pyæmia may deceive even a physician of ripe experience, especially if a cardiac complication, such as acute pericarditis, is an early sign, or if the pyrexia begins to subside after the administration of salicylate The presence of subcutaneous rheumatic nodules, erythema marginatum (Keil 1938) or erythema nodosum (Edström 1937) will help to exclude carditis of septic origin I have seen the initial phase of an intensely acute rheumatic carditis simulate enteric fever and abortus fever. In one case the onset of jaundice on the seventh day, yielding an icterus index of 33, suggested leptospirosis until that disease was excluded by agglutination and inoculation tests. The differentiation from acute tuberculosis seldom occasions any difficulty.

Prognosis

Except in fulminant cases the immediate prognosis is usually favourable; but it is grave if the aortic as well as the mitral valve become affected, if the pyrexia be prolonged for several weeks, if pronounced tachycardia persist after the patient has become afebrile, and if the heart fail and the lungs and liver become congested and the lower limbs dropsical. Even such a patient, however, may survive the acute phase of the disease and be leading a useful and happy life several years later. Sodium salicylate is powerless to arrest or to mitigate carditis; the efficacy of scarlet-fever antitoxin and other forms of serotherapy and of subcutaneous injections of hæmolytic streptococcal endotoxin is still open to doubt. Sulphanilamide is, I am convinced, not merely ineffective but also may aggravate the arthritic pains and increase the temperature.

A final opinion cannot yet be given upon the prognostic significance of electrocardiographic abnormalities in acute rheumatic carditis. Some writers (Robinow et al. 1936, Bland and Jones 1938) regard them as of little or no value; others (Grenet et al 1939) comment on the grave significance of S-T abnormalities persisting for more than a month, auricular fibrillation, and progressive deviation of the electric axis In my opinion the prognosis in this, as in all other affections of the heart, should never be founded solely or even mainly upon any one method of studying the morphological and functional state of the organ

While still under my observation 26 patients (9 7 per cent) of the series of 268 died, 14 being between the ages of eleven and twenty-five and 8 being over twenty-five; 9 died during a first attack of rheumatic fever, 3 had one attack before the fatal recurrence, 8 had repeated attacks, and 6 died of congestive heart-failure without any fresh clinical manifestations of rheumatic fever This classification (Gross and Ehrlich 1934) is misleading in respect of the fourth group, because at least 2 of the 6 patients in that group had acute carditis implicating the tricuspid, mitral, and aortic valves, this being in accord with the well-established fact that in a high percentage of fatal cases of rheumatic heart-disease there is active carditis which has seldom been recognised during life.

Morbid Anatomy

Fourteen cases were examined post-mortem by *Prof A. Murray Drennan and members of his staff*, to whom I gladly acknowledge my indebtedness for help in this investigation Even although there are obvious rheumatic lesions of the pericardium and cardiac valves, it is exceedingly doubtful if acute rheumatic carditis can be recognised without microscopical examination.

HEART

The anatomical changes in the heart are due in various degrees to (1) non-specific exudative, degenerative, and infiltrative processes comparable to similar changes in tuberculosis; (2) lesions of mesenchymal cells of connective tissue—the "connective-tissue skeleton" (Poynton 1928, 1936)—and of blood-vessels, leading to the formation of the specific granuloma, Aschoff nodule, or Aschoff body; (3) *vascular lesions*, and (4) *lesions of myocardial fibres* The degree to which these changes attain varies greatly in individual cases according to the intensity and duration of the disease.

(1) *The non-specific changes* are similar to those in other states of infection, toxæmia, and the hyperergic response to foreign protein (Klinge 1933a). We constantly find *fibrinoid degeneration of collagen* connective-tissue fibres, mainly perivascular in distribution, œdema usually more diffuse, and leucocytic infiltration. These changes, which collectively represent the Arthus phenomenon (Werner 1938), begin concurrently, before any specific rheumatic lesions have developed, yet may persist throughout. Fibrinoid degeneration was most intense in the heart of a woman, aged thirty-two, who succumbed ten and a half weeks after the onset of rheumatic fever Œdema of the myocardium, analogous to exudation of fluid into a joint, was particularly severe in a girl, aged nine, who had extensive rheumatic vegetations on the mitral valve. The cellular infiltration, mainly lymphocytic, is sometimes scanty

and at others intense, especially in and near the attachment of the cusps of affected valves. Fatty change in myocardial fibres is common. Necrosis is rare, it was most pronounced in a boy, aged fourteen, whose final recrudescence of rheumatic fever with endocarditis of mitral, aortic, and tricuspid valves lasted a month.

(2) *The specific rheumatic granuloma*, or Aschoff nodule, was sought for in 12 and found in 9 cases, abundantly in some and scantily in others. These microscopic nodules are more numerous in the ventricles than in the auricles, to this rule there was one exception. Lying usually in close proximity to myocardial arterioles, less often subserous, they consist of basophilic mesenchymal cells, some of which are multinucleated giant cells, and of collagen which has undergone fibrinoid degeneration and stains deeply with eosin. At first spherical, the nodules become successively oval and fusiform, gradually they become fibrosed, and late involution forms are represented by scars.

Following Klinge (1933*b*) we may differentiate young nodules less than four weeks old from those more mature and from late involution forms. Nodules in various stages of development, young and old, may often be seen in one and the same section. No attempt was made to classify nodules according to the criteria laid down by Gross and Ehrlich (1934), who recognised seven types, but the "mosaic" forms in perivascular, endocardial, and subendocardial sites can readily be distinguished from "reticular" forms in loose connective tissue. At the periphery of a nodule and around it there is sometimes a zone of lymphocytic infiltration. In acute cases, especially those ending during the ninth week of a first attack of rheumatic fever, the cells of the nodules are said to undergo fusion and great enlargement, forming "huge syncytial masses" which surround the scanty central collagen material (Gross and Ehrlich 1934). There was no case of this nature in my series. The Aschoff nodule, which must not be mistaken for a focal aggregation of leucocytes, is almost universally considered to be specific for rheumatic fever, as is the Langhans giant cell system for tuberculosis and the Greenfield (1878) multinucleated cell system for lymphadenoma. Subcutaneous rheumatic nodules have essentially the same structure as Aschoff nodules in the heart. Widespread dissemination of nodules in the pharynx, larynx, trachea, œsophagus, and elsewhere has been reported (Sarafoff 1932), a search for nodules in those sites in one of my cases proved fruitless.

If a case ends within a fortnight of a first acute rheumatic attack, Aschoff nodules, it is said, have not yet developed, only initial non specific inflammatory lesions will be found (Klinge 1933*b*), and they will be widespread if the disease has been particularly severe (Skworzoff 1938). Indeed, non specific exudations and infiltrations and gross destruction of muscle-fibres are regarded by Fahr (1938) as the morphological basis of hyperpyrexic rheumatic fever. In a man, aged thirty four, who developed wild maniacal delirium when the temperature rose to 106·7° F. on the fifteenth day of a recurrence we found fully formed but not fibrosed Aschoff nodules with small perinodular zones of leucocytes and considerable œdema of the myocardium but little fibrinoid degeneration and no serious destruction of muscle fibres. In a woman, aged twenty five, whose temperature rose to 108·8° F. on the seventh day of a first attack of rheumatic fever we found many young Aschoff nodules but, except for œdema, few non specific changes. In three hyperpyrexic cases a large soft spleen and numerous small subpleural or subepicardial hæmorrhages, and in one a large subendocardial hæmorrhage, indicate an analogy between hyperpyrexial rheumatic fever and an acute septic infection.

(3) *Vascular lesions* of the coronary arterial system are common. Most of them are non specific and of similar nature to those in many general infections, as described by Cowan (1904). His early observations have been extended by many subsequent writers, notably Coombs (1908–09), Perry (1930), who has shown that in rheumatic fever the whole of the coronary tree is liable to be damaged, Klinge (1933), Chiari (1938), and Karsner and Bayless (1934). In a girl, aged seventeen, whose death was due to a third recurrence of acute rheumatic carditis the main coronary arteries showed diffuse unequal intimal thickening with patchy hyalinisation of the media, sparse round cell infiltration, and fragmentation of the elastica. Intimal hyperplasia of small myocardial branches, whereby their lumen becomes greatly reduced, is a common but not invariable lesion. Intimal œdema was most conspicuous in a girl, aged nine, an acute monocyclic case of five months' duration. Medial œdema, causing the "reticular state" described by Rabé (1902), was best seen in a girl, aged eleven, whose kidneys were the seat of cortical necrosis. In the adventitia we find œdema and hyperplasia, it is in the adventitia of myocardial arterioles that Aschoff nodules usually develop. The coronary lesions are not identical in each case or in all parts of the coronary tree. They may be mainly intimal in some vessels and medial in others, there may be gross œdema of the myocardium yet little œdema of the walls of coronary branches. In none of my cases was there *necrotising arteritis* (Gross, Kugel, and Epstein 1935) or thrombosis with myocardial infarction (MacCallum 1923, Schwarz 1932).

Although the coronary vessels are more often and more seriously implicated than other portions of the vascular system, similar but usually less intense lesions may develop in any part of the aorta (but mainly in its abdominal portion) and in the pulmonary arteries and mesenteric arteries (Chiari 1932, 1938). More than thirty years ago Huchard (1905) recognised acute rheumatic aortitis. Pappenheimer and VonGlahn (1927) described a diffuse reaction of the intima and subjacent part of the aortic media, comparable to that of the auricular endocardium (MacCallum 1925), and focal lesions following the distribution of vasa vasorum which have been shown to penetrate the wall of the aorta and other arteries from within as well as from without (Winternitz et al. 1938). Infiltration of all three coats of the aorta with cells, mainly lymphocytes and plasma cells, and "mucoid" swelling and cystic change of the media, with fibrinoid and œdematous swelling of connective tissue and occasional Aschoff nodules, are reported by Klinge and Vaubel (1931), Schulz and Klinge (1933), and Lieber (1937). At the root of the aorta and that of the pulmonary artery the commonest lesion, according to Kugel and Epstein (1928) is a diffuse cellular infiltration, which, they suggest, may account for some of the transient auscultatory signs arising during rheumatic fever. Relative pulmonary incompetence in that disease has been ascribed by Scherf (1930) to these lesions. I cannot recall any case of this nature, but a comparable defect at the aortic valve, which was intact at autopsy, once came under my notice. Fibrous scars in the walls of aorta and pulmonary arteries may be found in the subjects of old inactive rheumatic disease (Wild 1933, Rössle 1933).

(4) *The myocardium*.—Attention has already been drawn to the all-important matter, the state of the myocardial fibres. Granular degeneration, fatty change, hyalinisation, and atrophy are often seen; necrosis is less common and less extensive. The formation of Aschoff nodules in the valves of the heart and their subsequent fibrosis may be as significant as the non-specific inflammatory changes in causing rheumatic valvular defects; but the clinical manifestations of myocardial weakness are to be ascribed not to the development of Aschoff nodules in the walls of the heart but to the action of a rheumatic toxin on the myocardium and to its ischæmia consequent on non-specific exudations, degenerations, and infiltrations.

BRAIN

Although the heart is the organ most often injured by rheumatic fever, there is a close association between acute rheumatic carditis and rheumatic affections of other viscera, notably the brain, lungs, and kidneys. The character and multiplicity of the cerebral lesions in Sydenham's chorea (Gamper 1935) lie beyond the scope of this lecture, but reference may be made to other cerebral affections. In 10 cases of the present series there developed delirium and other acute psychoses, which passed off except in 1 fatal hyperpyrexial case. There was cerebral embolism in 1 case and cerebral œdema in 1, a man, aged forty-one, who had a terminal epileptiform seizure. A case of much interest was a girl, aged thirteen, who developed headache, rigidity of the neck, and a meningitic cry twelve hours before death. In the frontal and parietal cortex of both sides Dr A. C. P. Campbell found multiple small (1–2 mm.) foci of ischæmic degeneration, some recent, showing pyknotic and necrotic nerve-cells without glial reaction, and others older, showing contraction and fibrous gliosis. Arterioles here and there were plugged with granular eosinophil masses of thrombus, presumably embolic. There was no sign of meningitis. This case, which resembles one of Edström's (1937), was not one of subacute bacterial endocarditis, in which infarcts are common, the clinical history and the lesions in the heart were characteristic of rheumatic carditis. In similar cases of "cerebral rheumatism" endarteritis of small cerebral vessels and acellular areas in the brain have been recorded by Winkelman and Eckel (1932).

LUNGS

Specific rheumatic lesions are seldom found in the lungs (Debré et al. 1937) but may be seen in the interlobular septa (Fraser 1930). Neither they nor the subpleural hæmorrhages in fulminant cases cause clinical symptoms. Non-specific processes are more important and have been regarded as integral components of the disease (Gouley 1937). Acute pulmonary œdema, due to left ventricular failure, is rare; I have seen 2 cases; both ended fatally. Chronic venous congestion and œdema of the lungs are commoner. In severe cases of acute rheumatic carditis we may find collapse of the lower lobe of the left lung from compression of the bronchi by pericardial effusion or a greatly dilated heart; reflex immobilisation of the diaphragm has been claimed as another causal factor (Coombs 1924). In respect of its site, physical signs, and clinical course this basal pulmonary collapse is virtually identical with the condition termed "rheumatic pneumonia." This was observed in 9 patients, their ages ranging from seven to twenty-nine. The patch of consolidation, which is almost always at or near the angle of the left scapula, may be extensive or no larger than a half-crown piece. The X-ray appearances of the left lung field may indicate merely venous congestion (Gouley 1937) or be sufficiently distinctive to confirm the clinical diagnosis of consolidation. All 9 patients were gravely ill; of 6 who survived 1 was playing football six months later despite mitral stenosis. In a girl, aged fifteen, with dry pericarditis and a greatly dilated heart the left lower lobe was found at autopsy to be merely congested. In another fatal case, a girl, aged nine, with a greatly enlarged heart but no pericarditis, there was likewise no consolidation of the lung. Neither case presented lesions intermediate between infarcts and pneumonia (Mallory 1935) or firm patches of acute interstitial pneumonia "like solid indiarubber" (Fraser 1930). In other cases of "rheumatic pneumonia" there is gross hæmorrhage in the pulmonary tissues (Bland and Jones 1938), or there are focal areas of "splenisation"—namely, intense hyperæmia and proliferation of cells of alveolar walls (Melnick 1938) and their capillaries (Naish 1928). Proliferative alveolitis and intimal desquamation, followed by fibrinoid necrosis of the walls of alveoli, alveolar ducts, and bronchioles (Debré et al. 1937), and fibrinoid alveolitis with formation of hyaline membranes in the alveolar ducts, a process similar to that of acute fulminant pneumonia in influenza and of pneumonic plague (Hadfield 1938), have been recorded. Acute bronchopneumonia was observed in 2 cases and infarction of the lung in 2 others.

Pleurisy was found in 8 cases, and in 6 of these there was a sterile pleuritic effusion. The prognosis in these cases is almost invariably grave, but a boy, aged sixteen, was apparently well five months later. I have never seen either rheumatic pleurisy or rheumatic consolidation of the lung except in association with serious rheumatic carditis, failing which a provisional diagnosis of acute rheumatic disease of pleura or lung had always to be abandoned.

KIDNEYS

There is seldom clinical evidence of any renal affection except transient albuminuria during febrile phases of the illness. Even in fatal cases of acute rheumatic carditis microscopical examination of the kidneys sometimes discloses no abnormality. They were diseased in 4 of my cases.

CASE 1.—A woman, aged twenty-eight, who had experienced an initial attack of rheumatic fever at fifteen, was suffering from a second attack with severe polyarthritis and signs of acute and chronic carditis but no dropsy. The daily excretion of urine seldom fell below 1 litre and occasionally it rose to 2 litres. The urine was sterile and contained albumin, blood, and epithelial and granular tube-casts throughout her stay of ten weeks in hospital. The blood-urea nitrogen was 19–22 mg., the non-protein nitrogen 37–41 mg., and the creatinine 3·3–3·6 mg. per 100 c.cm. The arterial blood-pressure varied from 130/70 to 100/70.

CASE 2.—A thirty-five a miner suffered from rheumatic fever. At thirty-nine he was febrile and breathless and he passed 1100–2200 c.cm. of urine daily, which contained albumin and blood. The kidneys showed old focal scars and recent glomerular changes—namely, cell-proliferation, thrombosis in tuft vessels, and adhesion to capsule. The mitral and aortic valves showed acute and chronic rheumatic valvulitis, and many Aschoff nodules in various stages of development were seen. The glomerular lesions in this case resemble those described by Bell (1932), who found a moderate degree of acute diffuse glomerulitis in 21 per cent. of 101 cases of active rheumatic carditis.

CASE 3.—A girl, aged seventeen, who had suffered from rheumatic fever at twelve, thirteen, and sixteen, had an acute exacerbation which ended fatally in four months. During the terminal three weeks the face was pale and puffy and the urine contained albumin and traces of blood. The blood-urea nitrogen was 35 mg. per 100 c.cm. There was acute diffuse inflammation of the glomeruli, their tufts were swollen and highly cellular, the excessive cells being round cells or proliferated endothelium, and there were no vascular or interstitial changes in the kidneys.

Acute glomerulonephritis, whether of toxic origin or secondary to non-specific vascular lesions, is rare in rheumatic fever. Goldring and Wyckoff (1930) did not find nephritis in any of their 16 patients, Bachr and Schifrin (1932) found 1 example in 118 cases, Fishberg (1939) saw only 2 undoubted cases, in Edström's (1937) 850 cases there were 17 of acute glomerulonephritis, Klinge (1932) has observed a series of cases with focal glomerulonephritis and subacute diffuse glomerulonephritis with hæmaturia, tube casts, and retention of nitrogen. Acute nephritis was found in 10 of Salveson's (1938) 212 cases of rheumatic fever. The nephritis is usually mild, takes a favourable course, and ends in complete recovery, but 2 of Salvesen's cases developed uræmia, and Loeb's (1931) patient, that of Bachr and Schifrin (1932), and 4 of Edström's (1937) patients died of uræmia.

Vascular lesions in the kidneys are also seen apart from glomerulonephritis. VonGlahn and Pappenheimer (1926) regarded exudation of fibrin with destructive and cellular changes in and around the vessels as specific. Klinge (1933c) constantly finds perivascular lymphocytic infiltration, especially in the cortex, glomeruli, arteries, arterioles, and veins may be surrounded by dense zones of lymphocytes. In 1 of his cases there were perivascular cellular nodules, like berries hanging on a stalk, with arterio- and arteriolo-necrosis of adjacent vessels, as previously described by Fahr (1921). The endothelium may be swollen and proliferated (Bachr and Sacks 1923), but intimal lesions are inconstant (Blaisdell 1934). Rheumatic granulomas in the kidney are exceedingly rare, it is doubtful if they alone ever cause glomerular and tubular lesions.

CASE 4.—A girl had rheumatic fever at eleven. At thirteen she suffered from a second attack with carditis. A year later congestive heart failure with dropsy supervened. The mitral and aortic valves showed acute and chronic valvulitis, there were acute rheumatic vegetations on the tricuspid valve; and in the myocardium were old and recent Aschoff nodules but no vascular lesions. Both kidneys showed cortical necrosis extending inwards to a depth not exceeding 2 mm. In the cortex were also acute cellular foci resembling the perivascular nodules described by Klinge (1933c). Reference has already been made to the focal cerebral lesions in this case. There was no indication of the cortical necrosis being secondary to thrombosis in cortical vessels and glomeruli, or of necrosis and fibrinoid degeneration in the walls of interlobular arteries, as described by von Zalka (1933).

So far as is known, the only previous case of cortical necrosis of the kidneys in acute rheumatic carditis was one in which the renal arteries were the seat of proliferative and necrotic lesions of such intensity that necrosis of the entire cortex of both kidneys ensued (Sacks 1925–26).

The other abdominal viscera are less often affected. Jaundice, a rare complication, may indicate a rheumatic hepatosis rather than hepatitis. Granular, fatty, and necrotic changes of liver cells are not specific. Aschoff nodules have been found in the capsule of the liver (Klinge 1932). There may be nodular hyperplasia and necrosis of the intima of veins within the organ (Rössle 1933), and a similar endophlebitis has been found in the spleen and pancreas (Coronini and Oberson 1937).

Conclusions

To what conclusions does a study of acute rheumatic carditis lead us? We realise more fully the risk of cardiac lesions arising during the course of rheumatic fever. It is true that in some cases those lesions must be transient, because life assurance companies subsequently accept those lives as first class and old age is attained in the enjoyment of good health. At the other extreme is the grave case in which profuse lesions in the walls of the heart and one or more of its valves lead to a fatal issue. If the patient survives the early acute phase, the cardiac lesions have presumably been less intense and less extensive, but he will almost certainly become a cardiac cripple. Even although the valves remain intact, the myocardial lesions may lead to fibrosis and thus to hypertrophy and dilatation of the heart without any valvular fault that might entail an increase of the heart's work. Further, the more we know of the vascular and visceral changes in rheumatic fever, the better do we realise that the damage is not confined to the heart but may be much more extensive. I have never been able to subscribe to the rheumatic origin of peritonitis (Poynton 1928), polyserositis (Edström 1937), mesenteric lymphadenitis (Ash 1936), acute appendicitis, and other abdominal disorders in childhood (Guptill 1934, Wolffe and Brim 1936), nor have I seen a "rheumatic aneurysm" (Edström 1937), but acute vascular lesions in coronary arteries and arterioles and in the aorta and pulmonary arteries may perhaps be the starting point of chronic degenerative changes in those vessels. Moreover various forms of granular contracted kidney, including malignant nephrosclerosis, it is thought, may be end-results of acute rheumatic vascular and glomerular lesions (Klinge 1932, Fahr 1938). The hypothesis that ascribes the origin of arteriosclerosis, as distinct from atheroma and medial calcification, to widespread rheumatic vascular lesions, systemic and splanchnic, has as yet little to commend it.

A deeper insight into the nature and extent of visceral rheumatism indicates clearly that the cardinal principles in the treatment and management of patients affected by rheumatic carditis should be followed as strictly and ceaselessly as is customary in the care of those who suffer from tuberculosis. Our goal, however, is not the treatment of the cardiac cripple but the prevention of rheumatic fever by a strict adoption of all appropriate measures of personal and social hygiene.

FAMILIAL ADENOMATOSIS OF COLON AND RECTUM

ITS RELATIONSHIP TO CANCER

BY J. P. LOCKHART-MUMMERY, F.R.C.S
EMERITUS SURGEON TO ST. MARK'S HOSPITAL, LONDON; AND
C. E. DUKES, M.D. Edin., M.Sc. Lond., D.P.H.
PATHOLOGIST TO THE HOSPITAL

IN adenomatosis of the colon and rectum (polyposis intestini) the whole mucosal surface of the rectum and colon is studded with innumerable adenomatous proliferations of the mucous membrane. The disease usually affects several members of a family and almost invariably leads to carcinoma.

A description of this disease, with the records of three families, given by one of us (Lockhart-Mummery 1925) concluded with the following summary:—

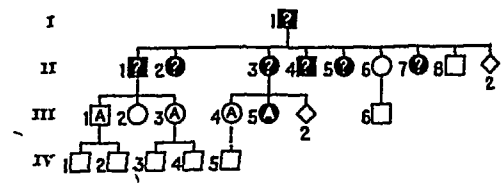
(1) Adenomatosis of the large bowel is a condition which tends to develop in succeeding generations in the same family. (2) Individuals with multiple adenomata of the large bowel almost invariably develop cancer in one or more of the adenomata after a few years. (3) The members of families with a hereditary tendency to multiple adenomata tend to die of cancer of the large bowel, and at an early age.

The experience of the last fourteen years amply confirms these conclusions. We have had an opportunity during this period of observing the course of the disease in ten families, whose history is recorded in the accompanying genealogical tables (families I–X), which very convincingly demonstrate the general familial character of the disease and its close relationship to cancer. The information set out in these tables has been derived from various sources. The starting-point in each case was a patient with adenomatosis. We obtained as complete a family history as possible from the patient, asking particularly about the present health or cause of death of parents, grand-parents, uncles, and aunts. Almost invariably we found that the patient was aware of the high incidence of death from intestinal cancer amongst his relations. We tried to get in touch with as many as possible of the surviving relations and to carry out sigmoidoscopic examinations. It was impossible to find out whether or not deceased relations had also been affected by adenomatosis; hence we have marked these cases with a ? in the tables to show that they died of cancer of the intestine, but that we have no information about adenomatosis. Probably in most cases the fatal cancer was secondary to adenomatosis. Some of the surviving descendants marked in the charts as unaffected may develop the disease in the future.

Although this disease is familial it does not manifest itself as a rule before childhood or puberty. The age at which adenomata begin to develop varies in different families. We tried to collect data on this point and in twenty cases obtained information which seemed to be reliable. The average age at which adenomata were discovered was 22. The youngest patient was 8 and the oldest 43. The tumours were probably present for at least a year or two before they were discovered; so the average age at which adenomata developed may be taken as about 20. In two families recently investigated by McKenney (1936) the average age was 19½.

Malignant disease secondary to adenomatosis is characterised by its early age of onset and the fact that more than one primary focus of carcinoma may

FAMILY I



I—(1) Death from cancer of rectum, aged 42.
II—(1, 2, 3, 4, 5, 7) Death from cancer of rectum, aged 46, 52, 54, 39, 27, and 44 respectively.
III—(1) Adenomatosis developed at 43 years, now aged 55, no sign of carcinoma. (3) Multiple adenomata found at 37 years, now aged 40; no sign of carcinoma. (4) Multiple adenomata found at 11 years, colectomy for adenomatosis at 31 years; no sign of carcinoma, now aged 46 and in good health. (5) Death from cancer of colon, aged 33.

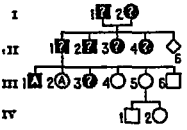
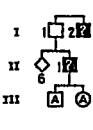
FAMILY II



FAMILY III



FAMILY II—I—(1 and 2) Death from cancer of rectum (ages unknown)

II—(1) Death from cancer of rectum, aged 44 (2, 3, and 4) Death from cancer of rectum (ages unknown)

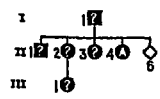
III—(1) Colectomy for multiple adenomata at 30 years, died from cancer of rectum, aged about 36 (2) Adenomata found at 14 years, colectomy at 25 years, now aged 46 (3) Death from cancer of the liver (age unknown)

FAMILY III—I—(2) Death from cancer of rectum, aged 60

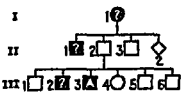
II—(1) Death from cancer of rectum, aged 46

III—(1) Treated for adenomatosis since 12 years of age, now aged 41 (2) Colectomy for adenomatosis at age 22, has remained well since (12 years)

FAMILY IV



FAMILY V



FAMILY IV—I—(1) Death from "cancer in pelvis," aged 62

II—(1) Death from cancer of rectum, aged 32 (2) Death from "abdominal growth," aged 45 (3) Death from cancer of rectum, aged 38 (4) Perineo-abdominal excision for cancer of rectum, aged 38; died from recurrence one year later

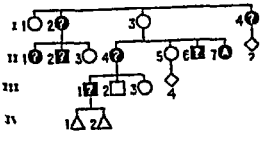
III—(1) Death from "abdominal" cancer (age unknown)

FAMILY V—I—(1) Died aged 40 after operation for cancer

II—(1) Death from intestinal cancer (age unknown)

III—(2) Death from intestinal cancer, aged 47 (3) Bleeding from rectal adenomata at 15 years, perineo abdominal excision for multiple carcinoma of rectum associated with adenomatosis at age of 38 (three separate malignant growths—see fig 3), alive and well 1¼ years later

FAMILY VI

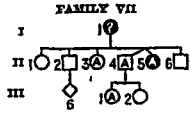


I—(2) Colostomy for malignant disease at 37 years, died 3 weeks later (4) Death from hepatic metastases

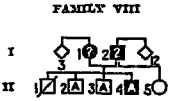
II—(1) Death from "abdominal" cancer, aged 50 (2) Death from cancer of intestine, aged 45 (4) Death from cancer of rectum, aged 53 (6) Death from cancer of rectum, aged 53 (7) Perineo-abdominal excision for cancer of rectum associated with adenomatosis, aged 53, alive and well 1½ years later (fig 2)

III—(1) Cancer of intestine, aged 23, treated with radium

FAMILY VII



FAMILY VIII



FAMILY VII—I—(1) Death from cancer of colon, age unknown

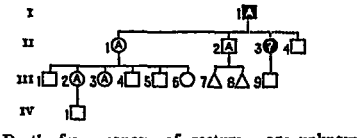
II—(3) Died aged 40, known to have suffered from adenomatosis (4) Symptoms of adenomatosis, aged 30, colectomy aged 41, died after operation, no sign of carcinoma (5) Twin sister of II (4), symptoms of adenomatosis developed at same age as twin brother, died, aged 41, from intestinal cancer

III—(1) Adenomata found at 14 years, now aged 17 and under treatment

FAMILY VIII—I—(1) Death from intestinal cancer, aged 41 (2) Death from cancer of colon, aged 50

II—(2) Multiple adenomata found at 24 years now aged 31 and under medical supervision (3) Colectomy for adenomatosis, aged 24, died after operation, no sign of carcinoma (4) Adenomatosis and inoperable cancer of rectum found at 21 years, died aged 22

FAMILY IX



I—(1) Death from cancer of rectum, age unknown

II—(1) Symptoms of adenomatosis at 21 years, patient now aged 50, no sign of carcinoma but has had several adenomata removed by local excision during last 7 years (2) Suffers from adenomatosis, now aged 49 (3) Death from carcinoma of colon, aged 32

III—(2) Symptoms of adenomatosis at 14 years, now aged 29 (3) Symptoms of adenomatosis at 8 years, now aged 27

FAMILY X

I—(1) Death from cancer of rectum, aged 42

II—(2) Colostomy for inoperable intestinal cancer, died 3 years later (6) Symptoms of adenomatosis at about 30 years, perineo-abdominal excision for adenomatosis at age of 37, no sign of malignancy (fig 1)

III—(6) Symptoms of adenomatosis at 17 years, now 18

EXPLANATION OF GENEALOGICAL TABLES

A Ⓐ	Male or female with adenomatosis
? ?	Male or female with cancer but not examined for adenomatosis
A Ⓐ	Male or female with cancer and adenomatosis
⊠ ⌀	Death in male or female offspring under 7 years
△	Sex unknown
⏃	Death in infancy, sex unknown
?	Siblings (brothers and sisters) not individually represented Number (if known) is indicated below, otherwise a note of interrogation is used

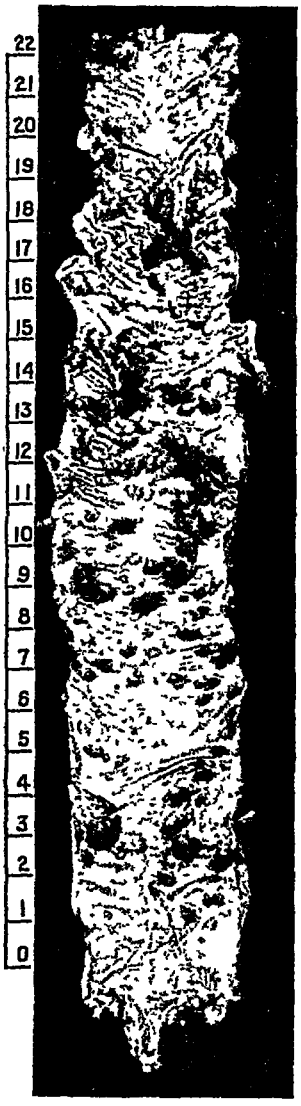


FIG. 1—Rectum and colon showing widespread adenomatosis (family X, II (6))

FIG 2—Carcinoma (indicated by arrow) associated with adenomatosis (family VI, II (7))

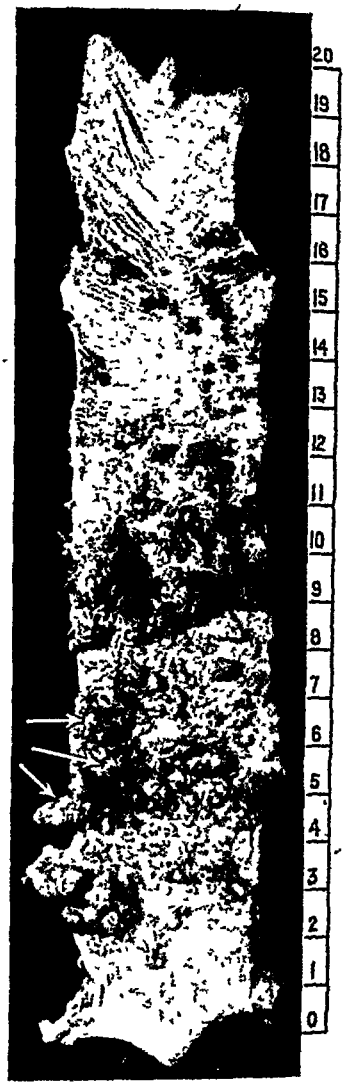

FIG 3—Multiple carcinoma (indicated by arrows) associated with adenomatosis (family V, III (3))

be present Among the general population it is rare for cancer of the rectum or the colon to develop before 40–50, but in families affected by adenomatosis it often begins to develop at 30–40 or even earlier. The age of death from cancer in adenomatosis families is also younger by about twenty years than the average age of death from this disease in the general population In these families the average age of death from cancer of the intestine was 42 The youngest was 22 and the oldest 60 In only a few cases were we able to collect reliable information about the exact age at which cancer began, but it was generally in the early thirties Although there may be considerable variation in different families, as a general rule in families affected by adenomatosis the tumours begin to develop about 20, malignant changes may be expected about fifteen years later, and untreated cases die from cancer in the early forties

It is obvious from the genealogical tables that the disease may be transmitted by either sex Since in most cases only one parent was affected, we have omitted from the tables the unaffected partner in the marriage In two cases, however, we have evidence that both husband and wife died of cancer (families II and VIII), and in both of these families most of the

FIG 4—Section through rectal mucosa in a case of adenomatosis (× 8)

descendants developed adenomata at an early age Family VII is also of special interest because of the presence of twins (generation II, 4 and 5) Symptoms of adenomatosis developed in both twins about 30 One was treated by colectomy at 41, but he succumbed to the operation His twin sister died of intestinal cancer also at 41

FIG 5—Section through rectal adenoma in a case of adenomatosis (× 10)

The appearance of the mucosa of the colon and rectum in adenomatosis is shown in figs 1, 2, and 3, and the histology of the adenomata in figs 4 and 5 The onset of malignancy can generally be detected by changes in the colour and consistence of the adenomata Tumours with active epithelial proliferation are always darker than quiescent growths, but, when cancer develops the growth becomes dark red or dark brown and much firmer than the surrounding adenomata It is common to find evidence of malignant degeneration in two or three different regions

The familial character of adenomatosis is obvious not only from these charts but also from the other cases reported by Dukes (1930) Most observers of this disease have concluded that the defect is inherited as a Mendelian dominant The disease is not congenital in the ordinary sense of the word, since it does not manifest itself for several years, but it is certainly due to an inherited defect, and the most likely explanation seems to be that it is caused by a gene mutation Evidence is steadily accumulating for the view expressed by one of us (Lockhart Mummery 1934) that tumours are the result of a genetic change in a normal growing somatic cell This explanation is applicable also to adenomatosis, in which disease the genetic defect appears to be a tendency to a more rapid growth of the intestinal mucosa, leading first to hyperplasia and later to adenomata This defect may be explained as a result of a gene mutation and the liability to it is handed on from one generation to the next The more rapid growth of the intestinal mucosa increases the probability of a further gene mutation responsible for malignancy, a change which can only take place when cells are undergoing mitosis Because of the more rapid growth of the intestinal epithelium there must be a greater frequency of mitotic division and this again increases the probability of a further gene mutation which manifests itself as cancer In a rapidly growing adenoma the chance of this happening is much greater than in normal mucosa where mitosis only takes place at comparatively rare intervals

Our explanation suggests therefore that familial adenomatosis is the result of an inherited instability of the epithelial cells of the large bowel which renders their nuclei peculiarly liable to undergo mutation for excessive rate of growth We regard the increased incidence of cancer of the colon and rectum as a secondary phenomenon dependent on the fact that mitotic division is more frequent in proliferating adenomata than in normal mucosa

The treatment of adenomatosis presents a difficult problem Constant medical supervision is necessary so that a radical excision may be undertaken as soon as malignancy is detected One patient in this series was treated by deep X rays to the whole large bowel It was doubtful if any real improvement resulted, and the progress of the disease was certainly not arrested Five cases were treated by complete excision of the colon, and four of these patients are alive and well This formidable operation may be indicated in some cases but is not necessary for all

We express our gratitude to all our colleagues at St Mark's Hospital who allowed us to consult the notes of their cases, to the doctors to whom we have written for further details of cases, and most of all to patients and relations who have cooperated by submitting to examinations and providing information. Much of the clerical work has been carried out by Miss S H Douglas, receiving a temporary grant from the British Empire Cancer Campaign, to whom we also express our obligations

BACTERIÆMIA FOLLOWING TONSILLECTOMY

BY S D ELLIOTT, M B Lond, D P H

DEMONSTRATOR IN PATHOLOGY IN THE UNIVERSITY OF CAMBRIDGE

DURING the last ten years at least six attempts have been made to determine the frequency with which bacteriæmia follows tonsillectomy (Rubin, Epstein, and Werner 1929, Schwartz and Frisch 1929, Bartlett and Pratt 1931, Wirth 1932, Fischer and Gottdenker 1936, Southworth and Flake 1938) My excuse for adding to them is the lack of agreement in the recorded observations The discrepancies, which range from a failure to demonstrate a single positive blood culture (Rubin et al 1929) to a 32 per cent positive rate (Fischer and Gottdenker 1936), may result from variations in the technique of blood culture and from differences in the time after operation at which a sample of blood was taken

TECHNIQUE OF BLOOD CULTURE

In the present investigation a technique has been used similar to that adopted in a previous inquiry into bacteriæmia following dental extractions, when many positive blood cultures were obtained within a few minutes of operation (Okell and Elliott 1935, Elliott 1938) This procedure allows of comparison between the relative frequencies of immediate blood-stream infection following these two types of operation, and it seems reasonable to assume that what proved to be the best moment for taking a sample of blood after dental extraction would be the best moment for taking it after tonsillectomy

Samples of 4–10 c.cm of blood were withdrawn from an arm vein immediately before and within five minutes after tonsillectomy Both specimens were taken while the patient was under the influence of a general anæsthetic—ether or gas and oxygen In a few instances a third sample of blood was taken a little later

Each sample of blood was divided into two or three equal parts, and these were inoculated into 20 c.cm. quantities of sodium citrate, Liquoid* (a synthetic polymer of sodium anethol sulphonate), citrate saponin, or saponin-liquoid broth. In the early part of the investigation citrate and saponin-citrate broth were used exclusively, but subsequently the citrate broth was replaced by liquoid and saponin-liquoid broth. The final concentration of sodium citrate, saponin, and liquoid in the blood-broth mixtures lay between 0·17 and 0·18 per cent., 0·042 and 0·017 per cent., and 0·017 and 0·019 per cent. respectively. The blood broths were incubated aerobically at 37° C. for seven days, after which subcultures were made on to 5 per cent. horse-blood agar and into 0·1 per cent. glucose broth; these subcultures were incubated for two days at 37° C.

In thirty-five subjects "pour-plates" also were made and incubated at 37° C. aerobically for seven days to obtain a count of the viable organisms if the culture proved positive. This procedure was subsequently discontinued, for, even when the blood-culture was positive, bacteria could never be demonstrated in numbers greater than 1 per c.cm. of blood.

BLOOD-CULTURES AFTER TONSILLECTOMY

Table I summarises the results of blood-culture immediately after tonsillectomy. In 14 cases an

additional sample of blood was taken for culture one to three hours after operation. *Staphylococcus albus* was isolated from 1 of these samples, which had been taken two hours after tonsillectomy; the blood taken for culture both before and immediately after operation was sterile. The remaining 13 samples were sterile, although positive blood-cultures had been obtained in 4 of these subjects immediately after operation. It appears, therefore, that the bacteriæmia following tonsillectomy is of short duration, as is the case after dental extraction. The organisms recovered in the 38 positive cases shown in table I were:—

Streptococcus (21).—These were classified in the first instance according to the appearance produced by surface colonies on 5 per cent. horse-blood agar. Hæmolytic streptococci were further identified by slide agglutination with type-specific antisera kindly supplied by Dr. F. Griffith. The following types were isolated in pure culture: type III, type IV (twice), type XII, and type XIII. On two further occasions hæmolytic streptococci were recovered which were not agglutinated by any of the type-specific antisera, although 1 of these cultures yielded an extract which gave a precipitate when tested with a group A (Lancefield) antiserum. The remaining "untypable" hæmolytic streptococcus did not correspond to group A, B, or C. Serological matches for the streptococci from the blood were found in cultures taken from the appropriate tonsils after removal in 4 of the 6 cases in which *Str. pyogenes* was isolated from the blood-cultures. In only 1 instance was there a failure to recover hæmolytic streptococci from the tonsil when such bacteria had been found in the blood after operation.

Of the non-hæmolytic streptococci, 2 cultures were bile-soluble and corresponded culturally and morphologically to *Str. pneumoniæ*. One belonged to type III but was not pathogenic for a mouse in a dose of 0·5 c.cm. of an eighteen-hour broth culture. The other did not correspond to type I, II, or III. The remaining non-hæmolytic streptococci were of the *Str. viridans* type.

Hæmophilus (6).—These organisms were identified by their morphological and cultural characters on simple nutrient agar, 5 per cent. horse-blood agar, and Fildes's agar. None grew unaided on simple nutrient agar, although 2 out of 4 cultures tested grew symbiotically with *Staph. albus* on this medium and apparently belonged to the "parahæmophilus" group. All the hæmophilic organisms isolated exhibited satellitism with *Staph. albus* on horse-blood agar, but none were hæmolytic.

Staphylococcus (5).—Of these organisms 3 were of the *albus*, 1 of the *aureus*, and 1 of the *citreus* type. None were hæmolytic for horse blood.

Corynebacterium (4).—All showed characteristic morphological and cultural characters on Loffler's medium. Two fermented glucose and sucrose, 2 fermented neither of these carbohydrates.

Bacillus (2).—The 2 aerobic spore-bearing organisms isolated from the blood were not investigated in detail.

The isolation of staphylococci, diphtheroids, and spore-bearing aerobic bacilli, organisms commonly found on the surface of the skin, is possibly to be ascribed, in some cases, to contamination.

PYREXIA FOLLOWING TONSILLECTOMY

In most of the patients who underwent tonsillectomy during the morning the temperature rose to 99°–100° F. by the evening but had fallen again to the pre-operative level twenty-four hours later. The occurrence and degree of pyrexia was not found to bear any obvious relationship to the existence of a demonstrable bacteriæmia or to the presence of any particular kind of organism in the blood-stream after operation. The blood was not examined for bacteria during the pyrexial period, but a similar rise in temperature had been observed in patients after dental extractions, when samples of blood taken at this time—i.e., four to nine hours after operation—had always proved to be sterile.

BLOOD-CULTURES BEFORE TONSILLECTOMY

In 64 out of the 100 cases in which the blood was examined after operation a sample of blood was taken for culture immediately before tonsillectomy. A similar sample was taken before operation in 18 cases from which no blood could be obtained after tonsillectomy. Of these 82 blood-cultures before operation 7 (8·5 per cent.) were positive, *Str. viridans* being recovered twice, *Staph. albus*, *Sarcina lutea*, *Bacillus subtilis*, a diphtheroid, and a mould once each. In 3 of these 7 cases a positive blood culture was also obtained immediately after operation, but the organism isolated from the second was always different from that recovered from the first sample, except once when *Str. viridans* was obtained from the blood taken both before and after tonsillectomy. Apart from this case, it seems probable that the

* Liquoid is the proprietary name given to this compound by its manufacturers, Roche Products Ltd.

isolation of bacteria from the blood taken before operation was due to contamination, for the same organisms were not found in the postoperative sample, whereas those isolated from the preoperative specimen were types commonly found on the surface of the skin

Comparison of different blood culture media.—Each sample of blood was distributed equally between sodium citrate, saponin citrate, liquoid, or saponin liquoid broth, and the results are shown in table II. Two samples of blood are omitted from consideration in table II, for they were inoculated only into saponin citrate broth, both cultures were positive. There was no evidence for the enhanced growth of any particular type of organism by any particular type of broth medium, except possibly saponin citrate broth from which hæmolytic streptococci were recovered 5 times as compared with 1 occasion on which they were recovered from liquoid broth in 5 blood cultures when both media were used in parallel.

CULTURES FROM TONSILS

In 137 cases cultures were made on 5 per cent horse blood agar from the surface and crypts of the tonsils after their removal. A sterile platinum loop was roughly passed over the surface and introduced into the crypts of each tonsil and then rubbed over the surface of a blood agar plate. Hæmolytic streptococci were isolated from 87 cases (64 per cent.), being present in profuse culture in 54. From 44 unselected cases in which the tonsillar cultures yielded a growth of hæmolytic streptococci an attempt was made to identify these organisms by the slide agglutination method. In 18 cases (86 per cent.) the streptococci corresponded to serological types found in group A (Lancefield), in 1 case to a type in group C, and in 1 to a type in group G. Of the remaining 4 cultures of hæmolytic streptococci 1 belonged to group A but could not be typed with certainty, and 3 cultures could not be typed and were not grouped (see table III).

DISCUSSION

A fair body of evidence has now accumulated pointing to the conclusion that transient bacterial invasion of the blood stream is a not infrequent occurrence usually unattended by serious consequences. This had appeared evident from the results of animal experiments and observations summarised by Haines (1937). Nocard drew attention to the fact that the serum of fasting horses was nearly always sterile whereas that of animals recently fed often contained bacteria. Desoubry and Porcher (1895) confirmed this in the case of dogs, and Griffith (1907), using a different technique, obtained similar results with calves and pigs. Fatigue and starvation are also factors which, in experimental animals, appear to facilitate the passage of organisms from the alimentary tract into the blood stream (Ficker 1905, Boycott and Price-Jones 1926, Cobbett and Graham Smith's unpublished observations). In man a condition of "subinfection" was postulated by Adami (1910), who contended that under normal conditions bacteria are carried in the blood stream and lymphatics from the intestine to the liver and mesenteric lymph nodes. In conditions of "chronic intestinal irritation," he said, that the normally occurring bacteriæmia is increased and the bacteria are visible as "abundant minute granules" in the liver cells and mesenteric glands. Lewis and Grant (1923) have brought forward evidence of a different nature suggesting an "almost physiological entry" of organisms into the blood stream of the average person.

Tissue injury in infected areas has long been established as the cause of transient bacterial invasions of the blood stream. The observations of Seifert (1925) on a large series of cases subjected to operation, re examination of wounds, or the changing of dressings in an infected area clearly demonstrated this. Similar evidence was brought forward by Burrington and Wright (1930), who made blood cultures from patients in whom there had been some manipulation in an infected urinary tract, and Lehmann (1926) recovered *Cl. welchii* from blood cultures made immediately after curettage in 18 out of 100 consecutive abortions. Operations in an area so heavily infected as the mouth would be expected to lead to bacterial showers in the blood stream, and these have been demonstrated in many patients immediately after the extraction of teeth, especially in the presence of severe gingival infection (Okell and Elliott 1935, Fish and Maclean 1936, Round Kirkpatrick, and Hails 1936, Southworth and Blake 1938, and Bulleid's unpublished observations). Furthermore, it has been shown that a minimal degree of tissue damage, such as is produced by the slight manipulation of a tooth in an infected socket (Elliott 1939) or by the chewing of hard sweets by a patient with infected gums (Round et al. 1936), will induce immediate though transient invasion of the blood stream, nearly always by streptococci of the *viridans* type. From these observations it seems fair to conclude that an almost constant "seepage" of organisms into the blood stream takes place from heavily infected tissue, such as the gums, which, in pyorrhœa are constantly submitted to mild degrees of trauma similar to that caused by the movement of a loose tooth in an infected socket.

It is not surprising, therefore to find that tonsillectomy is followed in a fair proportion of cases by a demonstrable bacteriæmia. The incidence of bacteriæmia after removal of tonsils appears to be about the same as after extraction of teeth in a "clean"

mouth (34 per cent) but considerably less than after extraction of teeth in pyorrhœa (76 per cent) On the other hand, the diversity of bacteria in the blood seems to be greater after tonsillectomy than after dental extraction, when non-hæmolytic streptococci are found almost exclusively. This may be correlated with the great variety of the bacterial flora of the tonsil as compared with that of the gums, where *Str. viridans* is almost always the predominating organism.

From time to time cases are recorded in which subacute bacterial endocarditis appears to follow tonsillectomy; instances have also been described of recrudescence of acute rheumatism or of acute nephritis after this operation. The foregoing observations indicate a possible source and mode of infection in such cases It is of interest that occasionally the causal organism in subacute infective endocarditis is of the hæmophilus or parahæmophilus group (Miles and Gray 1938), and that those organisms may be found in the blood after tonsillectomy. Of equal interest is the observation that pathogenic organisms such as *Str. pyogenes* may circulate in the blood for short periods and in small numbers without producing any observable ill effect.

The results of the tonsillar cultures here recorded suggest that some 60 per cent. of patients admitted to hospital for tonsillectomy carry *Str pyogenes* in the throat. This is not altogether surprising, for it must be borne in mind that most of these patients had diseased tonsils, although it was not customary to admit cases for tonsillectomy within six weeks of an attack of tonsillitis These observations are, therefore, not comparable with those of Hare (1935), who found *Str pyogenes* in 7 per cent. of throat and nose swabs taken from normal subjects A carrier-rate of about 60 per cent , however, among patients admitted to hospital for tonsillectomy emphasises the risk in otorhinological wards of streptococcal cross-infection, which a previous inquiry has indicated as happening not infrequently in the absence of special preventive measures (Okell and Elliott 1936)

SUMMARY

(1) A transient bacteriæmia has been observed in 38 out of 100 patients within a few minutes of tonsillectomy. (2) Bacteria were found in the blood regardless of whether the tonsils were removed by blunt guillotine or dissection. (3) The organisms isolated included *Str pyogenes*, *Str. viridans*, *Str. pneumoniæ*, *Hæmophilus influenzæ*, staphylococcus, and corynebacterium (4) Serological matches for *Str. pyogenes* recovered from the blood were isolated from the corresponding tonsils after their removal. (5) Hæmolytic streptococci were recovered from the tonsils of 87 out of 137 patients undergoing tonsillectomy (64 per cent) (6) Of 44 cultures of streptococci so isolated and examined serologically 39 (86 per cent) belonged to group A, 1 to group B, and 1 to group C (Lancefield). (7) The evidence for the common occurrence of transient bacteriæmias in man and animals and the possible bearing of these observations on the ætiology of subacute infective endocarditis are briefly discussed.

The preparation of this paper owed much to encouragement and advice from the late Prof C. C. Okell. My thanks are due to Mr. Alfred Walford, hon. surgeon to Addenbrooke's Hospital, Cambridge, for access to cases under his care, and to Dr. F. Griffith, of the Ministry of Health, for the use of type-specific streptococcal antisera. The work was carried out during the tenure of a grant from the Harmsworth Memorial Fund.

PRODUCTION AND PREVENTION OF CARDIAC MURAL THROMBOSIS IN DOGS

BY D Y SOLANDT, M D. Toronto, Ph D Lond

ASSOCIATE PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF TORONTO

REGINALD NASSIM, B M Oxfd, M R C P.

FORMERLY MEDICAL REGISTRAR, ST GEORGE'S HOSPITAL, LONDON; AND

C. H BEST, M D. Toronto, D Sc Lond., F.R.S

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF TORONTO

(From the Departments of Physiology and Physiological Hygiene, University of Toronto, Canada)

IN a previous communication (Solandt and Best 1938) the use of heparin in the prevention of experimental coronary thrombosis in dogs was described. It was recognised that, owing to the indefinite nature of the premonitory signs of coronary thrombosis in man, this procedure would have limited value as a means of preventing the thrombosis However, if administered after the thrombosis had occurred it would presumably inhibit the extension of the thrombus and it might prevent the formation of cardiac mural thrombi. As over 10 per cent. of the deaths from coronary thrombosis are caused by embolic sequelæ to mural thrombus formation, this latter possibility seemed worthy of investigation

The first objective of the present experiments was therefore to obtain, with absolute certainty, mural thrombus formation on a necrotic area. The second was to prevent such thrombus formation with heparin.

METHODS

Dogs weighing 5–15 kg. were used as the experimental animals. The tip of the left ventricle was chosen as a region of the heart favourable for the formation of large thrombi It is a site from which the blood-stream will have no great tendency to dislodge a thrombus, especially if the myocardium at the tip is rendered inactive

In previous studies on coronary occlusion it was found that simply tying the coronary vessels supplying the tip of the left ventricle did not, in over 100

5th–7th rib and right-arm lead over the costo-vertebral angle) previously investigated (Solandt and Best 1938). The resulting records furnished information on the site and degree of the myocardial damage.

RESULTS

Fig. 1A shows a mural thrombus formed in the left ventricle of a heart treated in the manner outlined above. Large pendulous thrombi were usually found 30 minutes after the injection of the sclerosing solution. Such thrombi were composed chiefly of platelets.

The results obtained from a series of animals on which the autopsies were performed 1½ hr. after the hearts were injected are summarised in table I. Macroscopic mural thrombi were present in every case.

It is worthy of note that, in the dog, any damage which prevents the contraction of the apical region

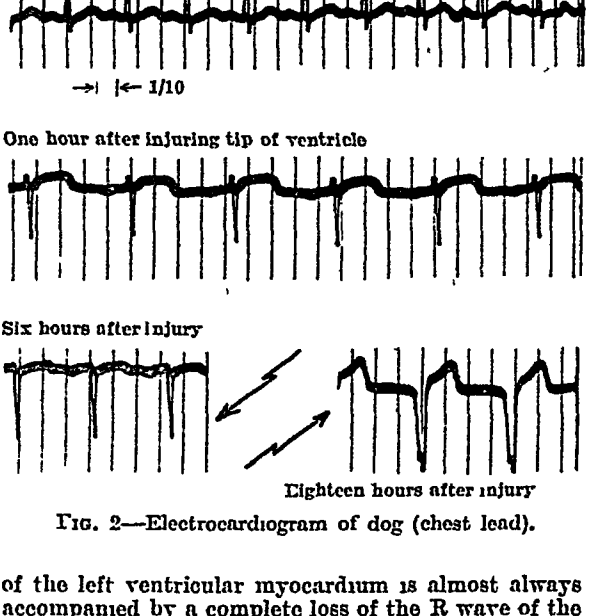

FIG. 2—Electrocardiogram of dog (chest lead).

of the left ventricular myocardium is almost always accompanied by a complete loss of the R wave of the electrocardiogram with the particular chest lead used. Fig. 2 shows the sequence of changes which culminate in this striking end-result. This confirms our previous observations (Solandt and Best 1938).

The results obtained on a series of animals treated as those in table I, except that heparin was administered as noted, are summarised in table II. A sterile and non-toxic solution containing 1000 units of heparin per c.cm., as supplied by the Connaught laboratories of the University of Toronto, was used in all our studies. No macroscopic thrombi were seen although microscopic clumps of platelets were present in many cases. The significance of this microscopic clumping will be discussed.

The results obtained from a series of animals on which the autopsies were performed 24 hours after the hearts were injected are summarised in table III. Again macroscopic mural thrombi were present in every case. A similar series which received heparin is described in table IV. Fig. 1B shows the tip of the left ventricle of the heart of an animal from this latter series. The damaged myocardium, necrotic endocardium and absence of mural thrombi are all very evident. No macroscopic or microscopic mural thrombi were found in this series.

DISCUSSION

It seems apparent from the foregoing results that, in the dog, heparin will prevent the formation of mural thrombi over grossly damaged endocardium. The damage produced was probably, in every case, much more severe than is ever seen in man as a result of occlusion of one or more coronary vessels. It seems reasonable to suppose, therefore, that heparin would prevent mural thrombus formation following a coronary thrombosis.

In the present experiments necrosis and thrombus formation started almost as soon as the sclerosing chemical was brought into contact with the myocardium. After coronary thrombosis it is probable that several days must elapse before necrosis becomes sufficiently severe to induce mural thrombus formation. Thus, in coronary thrombosis, one would expect to prevent the formation of a mural thrombus even if the administration of heparin was started some considerable time after the initial thrombosis. Just how long the heparin must be continued to permit a degree of healing such that further thrombosis will not occur when the heparin is discontinued is a matter which can be settled only by clinical trial. Murray, Jaques, Perrett and Best (1937) have shown that complete healing of the grossly damaged intimal layer of a vein takes place during heparin administration. It is reasonable to infer that the endocardium might undergo similar repair when thrombus formation over the injured area is prevented. To prove this point, however, a great many dogs would have to be sacrificed, since in animals which have undergone extensive operative procedures it is extremely difficult to prevent hæmorrhage from the cut surfaces when heparin is used.

A few of the hearts from the 1½ hr. heparin series showed microscopic clumps of platelets. These were never seen in the 24 hr. heparin series. In other experiments, not yet reported, we have evidence that the action of heparin on the agglutination of platelets takes longer to develop than does the effect on blood-clotting. In the 1½ hr. series the microscopic clumping of platelets could probably have been prevented by allowing a longer interval to elapse between the initial dose of heparin and the injection of the sclerosing solution. The clumps of platelets similar to those seen in this 1½ hr. series were probably also present early in the 24 hr. series. It is probable that they were washed away and were not replaced after the action of heparin on platelet agglutination had become fully established.

It has been suggested (*Brit. med. J.* 1938, Graybiel and White 1939) that heparin is contra-indicated in the prevention of coronary thrombosis where the initial vascular damage consists of a subintimal hæmorrhage as described by Paterson (1938) and Wartman (1938). Obviously this objection does not apply to the use of heparin in the prevention of formation of mural thrombi. In this case, as previously mentioned, the blood-clotting time need not be raised until some time after the thrombosis of the artery is complete; heparin has no effect on a thrombus already formed. However, we would like to take this opportunity to point out that the administration of heparin early in an attack of coronary thrombosis, even before the actual vascular thrombosis, is not necessarily contra-indicated in the light of the evidence at present available. It is not established that bleeding into a tissue space, such as the subintimal site mentioned, is stopped by blood-clotting. This

hæmorrhage is more probably checked by tissue pressure before clotting takes place, and the administration of heparin under such conditions should in no way extend or prolong the bleeding Obviously, however, this point can only be settled when extended clinical trials with heparin have been made We would like again to emphasise the fact that this objection to the use of heparin, even if valid, in no way involves its application in the prevention of mural thrombus formation

SUMMARY

1 A method is described by which cardiac mural thrombi may be produced in animals These thrombi form very rapidly

2 This formation of mural thrombi may be completely prevented by the administration of adequate amounts of highly purified heparin

3 Since over 10 per cent of the deaths associated with coronary thrombosis in man are caused by embolic sequels of mural thrombus formation, a clinical trial of heparin is indicated It would be useful to discover, by clinical investigation, the duration of heparin administration necessary to permit endocardial healing sufficient to ensure freedom from subsequent thrombus formation

It is a pleasure to thank Dr D L MacLean for the histological work involved in these experiments The technical assistance of Mr C R Cowan has been invaluable

MONOCYTIC ANGINA

(GLANDULAR FEVER) TREATED WITH M & B 693

REPORT OF A CASE AND EXPERIMENTAL TRANSMISSION

BY HUGH S STANNUS, PhD, MD Lond, FRCP
SENIOR PHYSICIAN TO THE FRENCH HOSPITAL, LONDON AND
G MARSHALL FINDLAY, CBE, ScD, MD Edin
WELLCOME BUREAU OF SCIENTIFIC RESEARCH, LONDON

THE history of the recognition of glandular fever and of the several clinical types to which this virus infection may give rise, together with the symptomatology and blood picture of the disease have been very clearly described by Letheby Tidy He mentions three types (1) glandular, (2) anginose, and (3) febrile (which might also be called the exanthematous type), and points out that cases of mixed type may occur

The case reported below belongs to the second group and is an example of the anginose type in pure form These cases are comparatively rare and may give rise to considerable difficulty in diagnosis in their earlier stages

CASE RECORD

The patient was a girl, aged 18 with little in her past history of interest, except that she had always disliked sun glare and was said to have suffered on two or three occasions from 'a touch of sun," the symptoms having been headache and nausea, accompanied by fever lasting a few days

On May 15, 1939, she went from London to stay in Paris During the last few days of that month she found the heat and bright sunlight rather trying, and she felt unduly tired On June 1 she felt definitely unwell and complained of headache and slight nausea. It was remarked that she looked ill She consulted a doctor in Paris, who diagnosed *un coup de soleil* She returned to London on June 3, her symptoms then consisting of fairly severe headache, an intense dislike of daylight, obstinate constipation, and feverishness

The patient first came under observation on June 7, the seventh day of her illness She lay in a completely darkened room and complained of intense headache but had no true photophobia, she was irritable and rather resentful of examination, the temperature was 102° F, pulse-rate 108, and respiration-rate 22 The face appeared rather puffy, especially about the eyes, the cheeks were flushed and the conjunctivæ slightly suffused The tongue was moist and but thinly coated The bowels had been opened the previous day with senna Detailed examination did not elicit any other signs Fundi oculorum normal, no signs referable to the central nervous system, the respiratory and cardiovascular systems were normal, the throat appeared healthy, there was no glandular enlargement or any evidence of enlargement of the liver or spleen, the kidneys were not palpable, nor was any departure from normal detected elsewhere in the abdomen, the urine contained no abnormal constituents

On June 9 serum reactions for *Bacillus typhosus* "H" and "O," *Bacillus paratyphosus* A "H," *Bacillus paratyphosus* B "H" and "O," and *Brucella abortus* proved negative A rapid examination of a blood-smear revealed nothing of interest

Between the 7th and the 12th, in spite of the continued pyrexia, the patient appeared remarkably well, the tongue remained almost clean, the headache was less severe, and the dislike of the light had passed, no fresh signs or symptoms had appeared. On the 12th a mildly irritable cough developed, and on the following day complaint was made of soreness of the throat and stuffiness of the nose, the fauces appeared red on examination

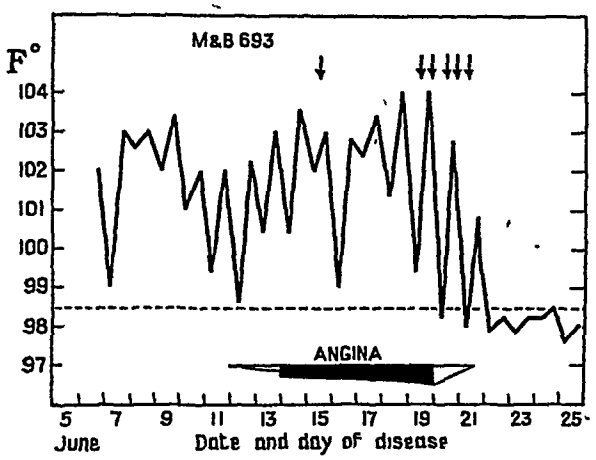
By June 14 (the fourteenth day of the disease) a rapid change had occurred, there was obvious swelling of the left side of the neck, and there was much œdema in the region of the left tonsil, which itself was much swollen, acutely inflamed, and covered by a diphtheritic-like membrane The tonsillar lymphatic gland was much swollen and tender, swallowing almost impossible, nourishment refused, and rest greatly interfered with, the patient showed some degree of anxiety The tongue was now thickly coated and the breath foul Cultures and smears from the throat showed the presence of the pneumococcus, *Staphylococcus aureus*, *Micrococcus catarrhalis*, and spirochætes of the Vincent type The temperature had reached over 103° F, but still the patient appeared comparatively well

Further laboratory investigations carried out by Dr H Schwabacher proved the blood and urine to be sterile on culture Serum reactions as above were repeated and again proved negative The following morning the local condition in the throat was worse, and the spleen was palpable This completed the clinical picture of the anginose type of glandular fever, confirmed by the report on blood examination received the following day red blood-cells 4,600,000, hæmoglobin 91 per cent, colour index 0·9; halometer reading normal, white cells 16,200 polymorphs 30 per cent, with a slight shift to the left, monocytes 66 per cent The Wassermann reaction was negative

Further confirmation of the diagnosis was made on the 17th, when the Paul Bunnell reaction (blood taken on the 14th) was returned as positive, lysis occurred in 1 in 640 dilution

Treatment.—At midday on the 15th an attempt was made to give M. & B 693 by mouth, but the vomiting resulting from the administration of one tablet (0·5 g.) was so severe that administration of the drug had to be discontinued Four days later, on the 19th, when the temperature had reached 104° F, and the condition of the patient was at its

worst, a second attempt was made, on this occasion by intramuscular injection. At 4 P.M. 0 5 g. of M. & B 693 in oily emulsion was given into the buttock and at 10 P.M. 1 g. of the water-soluble sodium preparation into the other buttock The temperature fell from 104° to 98° F. The following day (20th) the temperature rose to 102 8° F. in the evening; on that day two injections of the soluble salt, each of 1 g, were given into the gluteal muscles, at 12 noon and 9.30 P.M. The temperature fell to



Temperature chart At the first arrow the drug was given by mouth and at the following arrows intramuscularly.

98° F. On the 21st a fifth injection was given at 10.30 A.M. The temperature that afternoon only reached 100 8° F, to fall again on the morning of the 22nd and remain normal thereafter (see chart).

Very soon after the first injection cough became more pronounced, and a good deal of foul sputum, consisting of the products of disintegration of the tonsillar exudate, was coughed up. In a bout of coughing during the second injection at 10 P.M. and again on the evening of the next day the sputum was freely bloodstained. After the lapse of three days from the beginning of treatment the faucial condition had practically cleared up, and the patient could once more take nourishment freely and slept peacefully the night through, the first time for three weeks.

DISCUSSION

This case illustrates very well the clinical course of a case of glandular fever of the anginose type in uncomplicated form: a prodromal period of ten days (seven to fourteen) with headache and progressively rising temperature, obstinate constipation, but no other signs, and relatively mild constitutional disturbance followed by the complaint of sore-throat and then the extremely rapid development of an acute membranous angina with faucial œdema and swelling of the neck towards the end of the third week, splenic enlargement but no exanthem and no enlargement of superficial lymphatic glands or signs of involvement of the mediastinal or mesenteric glands. This forms a characteristic and diagnostic syndrome, the blood formula is pathognomonic, and the Paul-Bunnell test depending on the development of heterophil antibodies in the patient's serum may now be relied on as proof of the infection.

As far as we are aware, this is the first case of monocytic angina to be treated with M. & B. 693 Obviously it would be unwise to argue from a single observation, but the rapidity and the manner of the apparent response to treatment are very suggestive of a specific action of the drug in this infection The mode of fall of the temperature and the rapid resolution of the angina (which untreated may persist for a very much longer time), together with the rapid establishment of convalescence, were most striking On the other hand, the action of the drug may have been solely upon secondary organisms.

EXPERIMENTAL TRANSMISSION

Blood removed on the nineteenth day of illness was cultured aerobically and anaerobically on the more commonly employed bacteriological media and yielded no growth The culture medium, rich in serum, used for the isolation of pleuropneumonia like organisms also showed no growth

In recent years evidence has been accumulating that infectious mononucleosis is due to a filtrable organism

Bland (1931a and b) injected blood, taken during the febrile stage of infectious mononucleosis, into rabbits and produced a fatal infection. Heart blood, obtained from the rabbits, injected into rhesus monkeys caused fever, general lymphadenitis, enlargement of the liver and spleen, and a mononucleosis with primitive lymphocytes. Although Bland's experiments were complicated by the presence of *a toxoplasma, he certainly succeeded in causing in* monkeys a syndrome similar to that seen in human beings.

Later, van den Bergh and Liessens (1939) and Wising (1939) produced an infection in the rhesus monkey. Van den Bergh and Liessens injected a rhesus monkey intramuscularly with blood taken on the fourth day of illness. For the first three weeks the differential leucocyte-count showed little change, the percentage of large mononuclears being between 0 5 and 2 5. On the twenty-fourth day the large mononuclears were 13 5 per cent., on the twenty-fifth day 21·5 per cent, and on the twenty-sixth day 12 per cent. There was no febrile reaction and no definite enlargement of the lymph-nodes. The infection could be passaged in series, and the infective agent was filtrable through a Seitz pad. Wising (1939) also reported an increase in the number of mononuclear cells, together with adenitis and slight fever. During the course of the experiments a laboratory assistant was accidentally contaminated with blood from an infected monkey and after about seven days developed symptoms highly suggestive of infectious mononucleosis.

In the present investigation 4 c cm of whole blood from the patient was injected intramuscularly into a rhesus monkey. *Daily differential blood-counts* were made. The number of large mononuclear leucocytes varied from 1 5 to 4 per cent. for the first twelve days after injection Then on the thirteenth day after infection the number rose to 7 per cent. and on the fifteenth day to 28 per cent, falling on the sixteenth day to 12 per cent and remaining between 15 and 20 per cent till the twenty-first day after inoculation Blood-cultures taken from the monkey at the height of the mononuclear leucocytosis remained sterile The monkey at no time showed a temperature reaching 104° F., although the lymph-nodes in the axilla were a little more easily palpable during the period of reaction.

Blood from the patient, inoculated intracerebrally into mice, caused no evidence of illness, and no toxoplasmata were seen in smears from their tissues

Confirmatory evidence has thus been obtained that infectious mononucleosis is transmissible to the rhesus monkey Further observations are being made, especially on the action of chemotherapeutic drugs

CLINICAL NOTES

TREATMENT OF SPRAINS BY INJECTION OF PROCAINE

BY E L FRANKAU, M B Lond
RESIDENT MEDICAL OFFICER ACTON HOSPITAL

A SPRAIN is defined as a temporary subluxation in which the articular surfaces have returned to their normal positions and in which some damage has been done to the ligaments tendons or muscles around the joint The ligaments are most commonly affected This structure may be completely torn across or it may be avulsed from its attachment, when an extravasation of blood into the surrounding tissues can be observed, or in less severe injuries there may only be a partial tearing or stretching of the ligament, soon followed by œdematous swelling of the damaged tissues

The injury is always accompanied by intense pain, which may be localised to the site of the lesion or spread to involve the neighbouring parts According to Prof René Leriche an anatomically slight injury to the very sensitive nerve endings in the neighbourhood of joints starts a reflex, which begins with centripetal impulses from joint to central nervous system A vasomotor response follows, with local œdema and rise of temperature, pain and limitation of movement The disturbance of the local vasomotor equilibrium gives rise to continued impulses and a vicious circle is thus established

The treatment of sprains used to be most unsatisfactory Once fracture was excluded by radiography the treatment in hospital practice was usually left to the nurse or dresser who applied a tight bandage to the joint over some lint soaked in some cooling lotion, or the joint was strapped with adhesive bandage The rest of the treatment was left to the physiotherapy and massage department Though sprains are only minor injuries they may give rise to prolonged discomfort and invalidism and the average sprain in an adult, treated in this way, requires 2–4 weeks to heal

The recent treatment of sprains by injection of procaine into the injured ligaments is, as far as can be judged at this stage, a definite advance on the old treatment The centripetal impulses are cut off and abolished by the action of the local anæsthetic Thus the local vasomotor response is diminished or prevented altogether and somehow does not appear to reoccur to any marked extent even after the action of procaine has worn off Future work must show whether this theory is really in accordance with physiological facts

Technique—The ligaments of joints that are most commonly sprained are easily accessible The skin over the sprain is carefully cleaned with methylated ether It is now a matter of palpation to find for injection the most tender point This is marked and the injection made through it down to the ligament The strength of the solution of procaine is 2 per cent and 3 to 5 c cm are usually sufficient for a minor and 5–10 c cm for a more severe sprain The fluid is injected in various directions Thus the whole affected area is infiltrated After injection the part is lightly massaged, thus distributing the procaine evenly throughout the tissues With sterilised instruments and solution there is no risk of sepsis and an accidental intravenous injection can be avoided by the usual precautions Injection may have to be repeated on the second or third day if the result after the first injection should not be satisfactory

A total of 20 cases of sprains has been treated, the patients' ages ranging from 11 to 65 They were allocated as follows radial collateral, 2, dorsal radiocarpal 3, volar radiocarpal, 1, ulnar collateral, 1, anterior talofibular, 8, calcaneofibular, 3, tibial collateral, 1, dorsal first metatarsophalangeal, 1 The average amount of procaine injected varied between 3 and 10 c cm Pain disappeared at once in 15 cases and was much relieved in 5 cases It did not return in 7 cases, recurring after one hour in 1 case, after 2 hours in 1 case, after three hours in 3 cases, after four hours in 1 case, after five hours in 1 case, and after six hours in 6 cases In only 2 cases was it necessary to give a second injection after twenty four hours

The effect of this treatment is dramatic All the signs and symptoms of a severe sprain may disappear in a few moments after procaine has been injected into the ligament of the joint involved If, for example, a sprain of the ankle is promptly treated, œdema, local heat, pain, tenderness and almost complete loss of function will quickly vanish and the patient will be able to walk home It is of advantage to inject the sprained part soon after the injury occurs, but also old sprains have been successfully treated in this way Pain usually returns 3–6 hours after injection It varies in intensity, and is usually less than the initial pain, though a few patients complained of more severe pain It then gradually passes off and completely disappears after 24–48 hours A slight ache and feeling of weakness in the joint may be noticed for 1–4 days after the accident After injection the joint is firmly strapped with Elastoplast and the patient instructed to use the limb carefully Exercise is better avoided for several days so that the patient may regain his sense of security and also to prevent a recurrence of the sprain This treatment has been successfully employed for sprains of the ankle and wrist joints, which are the sprains most commonly encountered Sprains of the knee joint and the smaller joints of the hand and foot have equally benefited by it and the results have generally been good and quite uniform with regard to recurrence of pain and final cure

SKIN GRAFTS IN THE CASUALTY DEPARTMENT

BY D N MATTHEWS, M Ch Camb, F R C S
SURGICAL REGISTRAR AT WESTMINSTER HOSPITAL

EVERY surgeon who has had charge of a hospital casualty department will remember patients brought to the hospital as a result of some accident in which an area of skin and fat had been lost, and will also remember that these patients had to tolerate painful dressings for many weeks before the wounds healed by granulation This note is to suggest a method by which both the pain and the waste of time can be avoided and a much better cosmetic result be produced than by allowing healing to take place by granulation

The cutting of a thin Thiersch graft and its application to the raw area will produce a healed wound after five days with no infection and no scarring, provided that the wound is not grossly infected when first seen, in which case it must of course be treated on the usual lines There are many wounds however which, although they are not technically

sterile, are quite clean enough to allow perfect healing of a graft applied to a raw area To advocate the grafting of a raw surface is, of course, to suggest nothing new, but I believe that to emphasise the simplicity of the procedure under local anæsthesia together with the fact that the patient is treated entirely as an outpatient will draw attention to a method of treatment which is sadly neglected.

The technique is simple and the rules are few, but *it is important to realise* that they must be obeyed with meticulous care if success is to be obtained The wound must be grafted as soon as it is seen and not allowed to wait until it becomes infected Any temporary dressing, with which it may be necessary to cover the wound during the journey to hospital must consist only of sterile gauze soaked in saline, and under no circumstances must chemical antiseptics be used

Forearm of a child, showing two healed areas on which a Thiersch graft had been applied five days before

The figure shows two areas on the volar aspect of a child's forearm soundly healed five days after the application of a Thiersch graft to a wound caused by broken glass The patient attended hospital a few hours after the injury and was grafted at once, the outer side of the right thigh was sterilised with spirit and an area large enough to cover the defect was blocked by the subcutaneous injection of 2 per cent procaine It is important to put the procaine under the skin and not into it, since intradermal injection makes the cutting of a graft almost impossible The area should then be rubbed in order to spread the local anæsthetic evenly under the skin, and about five minutes allowed for it to take effect, after which the graft may be cut with any skin knife Until a little experience has been gained in the "feel" of the skin after the injection of local anæsthetic the surgeon tends to cut a graft which is thin and ragged, so that it is as well to hold the knife as though a thick graft were required, when it will be found that the blade does not sink through the skin but merely cuts an epithelial layer of average thickness

The graft is fixed by marginal sutures to the raw area and both the donor and recipient areas are covered with a greasy Vaseline dressing (Tulle Gras is the best) backed up by swabs soaked in normal saline, the whole being firmly held in position by elastic plaster bandages It is as well to immobilise the grafted area, and in the case here illustrated this was effected by a plaster slab and a sling, but it is quite unnecessary to rest the leg and the patient is able to walk home without experiencing any pain. The dressings must be left untouched for five days, after which they are removed, when it is found that the donor area (leg) is quite healed and that the grafted area needs only the removal of the marginal sutures and the renewal of the greasy dressing for a further week

As is always the case, this patient experienced no pain in the raw area as soon as it had been covered with the graft, and the injury was at once reduced to a mere inconvenience, in that the patient had to rest her arm in a sling for a week. I have used this method for a wound on the dorsum of the foot when the patient walked out of hospital as soon as the graft had been fixed in position, and have found a perfect graft when the dressing was removed five days later, in spite of the fact that there must have been some slight movement of the two surfaces when walking A final recommendation for this method of treatment is the excellence of the cosmetic result, which is much better than can ever be obtained by allowing granulation to take place The graft requires about three months in which to take on the colour and texture of the surrounding skin, after which it will be found to be hardly visible

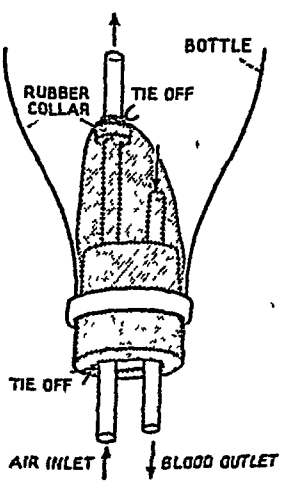
A NEW FILTER FOR BLOOD-TRANSFUSION

By MONTAGUE MAIZELS, M.D. Lond., M R C.P.
CLINICAL PATHOLOGIST, UNIVERSITY COLLEGE HOSPITAL, LONDON

When blood has been kept for a few days after collection, it is usual to filter it through glass wool or McCartney beads before transfusion. In my view glass wool is unsatisfactory. It is unpleasant material to work with, for it is liable to scarify the skin and to fragment easily, so that technicians preparing hundreds of such filters a day would be wise to wear gloves and a mask Packing the wool in the filter bulb requires considerable skill; if too loose or too tight, it is worse than useless The glass-wool filter is not easy to clean, especially if left for some time after use, and the removal of old glass wool and its replacement by fresh is a fiuicking procedure. The filter is efficient for blood which is fresh or only two or three days old, but it is liable to clog with tacky gelatinous material when used for blood that has been standing for a longer time

On the other hand gas-mantle fabric (before impregnation with incandescent salts and collodion) provides an efficient filter which may be used as an alternative to the glass beads or to replace the glass-wool filter.

The untreated gas-mantle of commerce consists of a knitted cotton tube with a purse-string tie-off at each end. It may be used as a filter in three ways —



(1) A common method of transfusion is to collect blood in a bottle containing sodium-citrate solution, and to fit the vessel with a rubber bung pierced by a long air-inlet tube and a short blood-outflow tube. The bottle is inverted and the blood is led into the vein of the recipient through a rubber tube and needle

To fit the mantle-filter a collar of narrow-bore rubber pressure-tubing is placed over the long air-inlet tube which it grips tightly. The mantle is drawn over the bung and its tubes and one of its purse-strings is tied above the pressure tube collar The purse-string at the other end of the mantle is drawn tight under the bung around the emergent glass tubes. The outfit may now be autoclaved.

The bung is then rammed into the neck of the bottle (see figure)

(2) If the mantle is shorter its lower purse string may be drawn tight over the upper end of the bung

(3) Another common method of administering blood is to pour it into a cylindrical funnel filtering it through a few layers of gauze awkwardly stuffed into the mouth of the funnel It is simpler to place a large mantle inside the funnel, turn the upper edge of the mantle over the upper rim of the funnel, and tie off the purse string just below the rim so as to hold the mantle in place

For method (1), mantles should be 3 in long by 1½ in wide (flat), for method (2), 1½ in by 1½ in, and for method (3) 8 in long by 3 in wide. They may be obtained from William Still and Sons, 29 Greville Street, E C 1, for a few pence

MEDICAL SOCIETIES

BRITISH MEDICAL ASSOCIATION

SECTION OF SURGERY

With Prof J R Learmonth (Aberdeen) in the chair, this section discussed

Treatment of Intractable Pain

Mr Norman Dott (Edinburgh) said pain was an indefinable term It was the reaction to a stimulus, but the strength of the reaction did not indicate the nature or severity of the stimulus It was the experience of bodily harm, and had its own anatomical pathway through the lateral nucleus of the optic thalamus Pain had two elements, affective and cognitive The affective element consisted of distress and fear and was experienced in the cerebral nuclei The cognitive element consisted of appreciation of localisation, temperature and area of contact, these were experienced in the cerebral cortex Pain was largely a protective physiological mechanism for example against overdistension of viscera but there were severe pains, such as headache and the pain of malignant disease, which were noxious without physiological reason These were the intractable pains Here the cause was either unknown or could not be removed In persistent pain, the thalamic centre which tended to prevent impulses reaching the cortex became exhausted The pain was produced in two ways First an abnormal stimulus itself caused the pain, as in the contraction of scar tissue, and the involvement of nerve endings in malignant disease Secondly, an innocent stimulus, such as touch or heat, might be perverted or augmented to feel like severe pain This was usually an axon reflex as in causalgia Occasionally a central lesion augmented or deranged stimuli, the most frequent cause was gliosis following trauma, disseminated sclerosis syringomyelia, or tumour Patients with these conditions were all susceptible to barometric changes Augmentation depended on four factors (*a*) *perversion*, when other forms of sensation such as cold or touch were perverted into the pain pathway, (*b*) *undue radiation*, when leakage of impulses occurred at the synapses, (*c*) *hypersensitivity*, when the inhibitory mechanism of the cortico thalamic region was out of action, and (*d*) *epileptiform facilitation* of the pain conducting system, paroxysmal or intermittent with only slight cause

Pain was sometimes conditioned by the individual, and there was evidence to believe in psychogenic pain Some viruses passed up along nerves and even across synapses as in herpes zoster, leading to permanent damage with trophic and vasomotor changes Trigeminal neuralgia was sometimes caused by inflammatory processes spreading from the accessory air sinuses Pain was localised to the side of the lesion only as far as the thalamus It was sometimes possible to infer the lesion from the type of pain felt In central types, it was advisable to assess the pain after peripheral impulses had been blocked by local or spinal anæsthesia If these relieved the pain, the treatment was obvious In post-herpetic neuralgia, blocking of the gasserian ganglion relieved the hyperæsthesia and paroxysmal pain, but often left a dull central ache Treatment of intractable pain was palliative Pain impulses were blocked either above the causative lesion, or below the lesion, when the pain was relieved by abolishing the facilitating stimuli

Mr T F Todd (Manchester) described his experience in 82 cases of intractable pain, mostly caused by carcinoma of the cervix He considered pain was intractable when natural sleep was impossible Visceral pain was relieved by presacral neurectomy, and somatic pain by intrathecal injection of absolute alcohol Intrathecal injection was quite safe if one knew the technique It was important to inject the alcohol slowly and limit the injection to not more than 1 c cm Occasionally it was followed by incontinence or retention, but this mattered less since all the cases treated were suffering from advanced malignant disease In several cases the posterior columns had been examined and found to show degenerative changes following injection The procedure was not recommended except for inoperable malignant disease

Mr J B Oldham (Liverpool) discussed pain of renal origin It was a relatively common complaint, and renal sympathectomy showed no untoward effects Intractable renal pain was probably due to spasmodic contraction of the smooth sphincteric muscle in the calyces and pelvis of the kidney, and there was possibly a vasospastic element Renal sympathectomy produced a kidney which was insensitive to distension, and frequently the size of the renal pelvis decreased He often combined the procedure with a plastic operation on the renal pelvis or nephropexy Afterwards there was a secretion of larger quantities of more dilute urine Pyelography was painless for about a year subsequent to the operation

Mr G F Rowntree (Manchester) spoke on the treatment of trigeminal neuralgia The operations available were avulsion or injection into the three main branches of the nerve, alcohol injections into the second and third divisions intracranial neurectomy of the three divisions root-section in the middle cranial fossa approached extradurally, section by intradural approach through the posterior fossa and lastly, intramedullary tractotomy Section or block in front of the ganglion gave good results but was sometimes followed by recurrence of pain after two years Root section was precise in its localisation, and anæsthesia of the cornea could be avoided In the extradural approach any facial paralysis was caused by damage of the greater superficial petrosal nerve and was transient Approach through the posterior fossa was sometimes technically difficult Tractotomy did not leave the face anæsthetic, but it

was a hazardous procedure and its only indication was in bilateral disease when keratitis had commenced in the other eye. As an anæsthetic he preferred basal narcosis combined with gas and oxygen. Probably the extradural fractional root-section through the middle fossa was the operation of choice.

Mr. D. W. C. NORTHFIELD (London) asked whether keratitis was more common following injection than operation and Mr. ROWBOTHAM replied that in his experience keratitis occurred sometimes after all the procedures he had described, but he thought that it was more common after injection.

Prof. LAMBERT ROGERS (Cardiff) suggested that keratitis was less common if thyroid extract were administered following the operation. Dr. GERALD SLOT (London) thought that much of the pain in trigeminal neuralgia was of sympathetic origin. He had used paravertebral injections of novocain with effect and had used A.B.A. for injections of the trigeminal ganglion. Dr. P. W. R. PETRIE (Loanhead) spoke of the psychogenic causes of headache. Mr. NORMAN LAKE (London) discussed philosophy of pain. There was no complete explanation of pain, nor why trivial lesions might cause severe pain when more serious damage was sometimes symptomless. There were some pains which did not appear to have any physiological use. Some races were more sensitive to pain than others. He thought that at least part of this was early education to know and fear pain.

Dr. W. McK. CRAIG (Mayo Clinic) also spoke on psychogenic pain. He hoped that someone would discover a method of measuring the intensity of pain so that it would be possible to estimate the relation between psychogenic and organic pain before an operation had to be considered.

Mr. C. F. MAYNE (Plymouth) asked if any nerve section had been found to alleviate the severe pain in carcinoma of the pancreas. Prof. C. F. W. ILLINGWORTH (Glasgow) said that the pain in carcinoma of pancreas was readily explainable in terms of the numerous retroperitoneal nerves in that area. He quoted a case of pancreatic cyst where pain was completely relieved by the removal of the cyst.

Mr. NORMAN DOTT, summing up, agreed that pain could not be assessed scientifically. Loss of sleep was not enough. He had placed great reliance on the patient's own story. He did not think keratitis was more common after one type of operation than the other. Psychogenic pain did not enter into his scheme of life at all. He thought that visceral pain was largely protective. He himself had found it to be protective against the evil effects of Aberdonian hospitality.

Arteriovenous Fistula

Mr. A. M. RENNIE (Aberdeen), introduced by Mr. Norman Lake, described four cases of congenital arteriovenous fistula. It was due to abnormal patency of embryonic channels between arteries and veins. Normally a few of these channels persisted and aided in the temperature regulating mechanism of the limbs. Often they gave no symptoms until adolescence, but might be shown up by trauma. The fistulæ tended to be multiple. They produced nutritional changes in affected part, and cardiac changes similar to those of aortic incompetence. In all the cases he had seen the arteriovenous communication was in the lower limb, which was considerably hypertrophied and longer than the healthy limb. Section of an affected saphenous vein revealed that the vein wall had become arterialised. The venous blood on the affected side was found to be highly oxygenated, and the temperature was several degrees higher than on the healthy side. No proper explanation had been given for the hypertrophy of the limb. Owing to the possible dangers, arteriography had not been attempted. Treatment was unsatisfactory because of the multiplicity of communications. Ligature and injection had been used, amputation, though a last resort, was frequently followed by great relief of the cardiac symptoms.

Mr. NORMAN LAKE suggested that uroselectan might be used to outline the vessels, and Prof. LEARMONTH said that injection into an artery was an extremely painful procedure and to get a good picture it would have to be carried out rapidly.

Water Balance

Mr. D. C. L. BINGHAM (Edinburgh) said that, in giving water and saline an adequate volume of fluid must be administered daily, and dehydration must be prevented or corrected. In normal metabolism, about 800 to 1500 c.cm. of water was lost through the skin. This was frequently greatly increased in disease. The urine was normally about 1000 to 1500 c.cm. Therefore the body required between 2500 and 3500 c.cm. of fluid daily in health. It had been found convenient to give a patient 2500 c.cm. of fluid during the first twenty-four hours after operation, by intravenous infusion with 5 per cent. glucose in distilled water, and to measure the amount of urine passed. If the urine was less than 1000 c.cm., more fluid was needed.

He recommended the preoperative administration of 1000 c.cm. of physiological saline before operations on the gastrointestinal tract. All abnormal fluid losses, such as from biliary or intestinal fistulæ, should be made good.

SECTION OF MEDICINE

AT a meeting of this section, with Dr. A. GREIG ANDERSON (Aberdeen), the president, in the chair, a discussion on

Prophylatic Immunisation

against diphtheria, whooping-cough, measles, scarlet fever and influenza was opened by Sir JOHN LEDINGHAM (London). He said that of these diseases diphtheria clearly merits chief consideration; first, because of the great toll it takes of child life, and secondly, because it has been demonstrated beyond question, though so far in countries other than this, that active immunisation intelligently and persistently carried out has actually brought the morbidity from diphtheria in certain localities down to zero. These methods depend for their success far more on propaganda directed towards securing the immunisation of all pre-school children than on the particular immunising substance employed. He urged that the fact that experience of the performance of these antigens both in the laboratory and in the field has not yet resulted in complete unanimity as to the best possible type of antigen and the ideal method of administering it should not be allowed to hold up schemes for applying our present knowledge in practice.

The investigation of an antigen for prophylactic purposes comprises a study not only of its potency, tolerability and the like when administered in a single dose but also of the effect of multiple doses suitably spaced. Many elaborate studies of these antigens, in particular of formol-toxoid (F.T.), alum-precipitated toxoid (A.P.T.) and toxoid-antitoxin floccules (T.A.F.) are, he said, on record, and an analysis of the data seems to suggest that either three injections of F.T. and T.A.F., or two injections of A.P.T., at intervals of at least a month, would greatly reduce the

incidence of diphtheria amongst the immunised Probably three doses of A P T would be the most effective of all, or one dose of A.P T followed by two of F T or T A F That the dose interval, and particularly the interval between the first and second doses, should be long rather than short, is a well-established finding in immunisation practice, whether in man, horse or guinea-pig He emphasised that while the immunisation of school children must be the first instalment of effort the ultimate objective should be the immunisation of the maximum number of children between the ages of 9 months and 2 years When such immunised children enter school a reinforcing dose seems desirable He said that suggestions likely to render immunisation against diphtheria more generally acceptable to parents and others responsible for the conservation of child life will be welcome, but he himself considered that some form of compulsion is the only remedy

Sir John Ledingham pointed out that in England and Wales whooping cough was responsible in 1937 for a death rate of 0 04 per 1000, as against 0 07 for diphtheria, while the corresponding rates for measles and scarlet fever were 0 02 and 0 009 Influenza with its death rate of 0 45 much exceeded these and, although the prospects of influencing its morbidity and mortality by prophylactic measures are not at the moment very hopeful, he felt sure that efforts to explore still further the possibilities of active immunisation will continue Immunisation against whooping cough certainly demands further exploitation and here again we have to turn to other countries and especially the United States of America for relevant data The results of some recent efforts strongly support the view that vaccines prepared from smooth organisms can confer a considerable degree of protection against pertussis In this country combined studies by public health officers and bacteriologists are much to be desired The gradual enlightenment of the public, by repeated demonstrations in its midst, of the benefits that immunisation could confer on children exposed to diphtheria and whooping cough would greatly facilitate progress We might envisage the immunisation of children with a mixed vaccine of smooth pertussis organisms and diphtheria toxoid, in the light of Ramon's demonstration that the addition of T A B vaccine to his diphtheria "anatoxine" in no way militates against the efficiency of either element

Dr D W Berry (Aberdeen) reviewed the present position of the prophylaxis of scarlet fever The usual method consists of the injection of diluted toxin subcutaneously five times at weekly intervals and in increasing doses The total dosage he said, should not be less than 20 000 skin test doses, and many prefer to give a total of 80,000 to 100 000 skin test doses Many parents refuse to have their children immunised in this way because of the frequent injections Reactions are more common than in the case of diphtheria immunisation and they sometimes take the form of "miniature scarlet fever" They can generally be avoided by making the initial injection a small one and increasing the dose gradually Dr Berry stated that there is no evidence that anti bacterial immunity resulted, the effects appear to be only antitoxic He suggested that this method of prophylaxis should still be used in those exposed to infection, and passive immunity with scarlet fever antitoxic serum reserved for use in children very badly exposed

Dr William Gunn (London) dealt with prophylactic immunisation against measles He stated that convalescent serum has given good results but that this is difficult to obtain in sufficient amounts when it is most needed At the beginning of an epidemic the demand is large, but a plentiful supply does not become available until the epidemic is subsiding He described a method whereby serum can be dried and then reconstituted when required The potency of serum treated in this way seems to be maintained for a long period Normal adult serum has been found to be about one third as potent as convalescent serum, but it is reasonably effective in modifying attacks Dr Gunn has found that immune globulin extracted from human placentas is not much more effective than adult serum and he has largely abandoned its use because of the reactions which sometimes follow He referred to the occurrence of severe toxic hepatitis with jaundice in some cases which had been treated with one batch of serum No satisfactory explanation has been arrived at, but a living virus may have gained access to that particular batch

Dr C H Stuart-Harris (London) said that the isolation of a virus from human cases of epidemic influenza raised hopes that some form of immunisation would be effective The virus can be isolated from most cases in large epidemics, but in small localised epidemics such isolation frequently fails There is a tendency for influenza of the virus positive type to be associated with a heavy mortality from pneumonia Dr Stuart Harris then described immunisation experiments in humans given injections of formolised virus Two years ago many people were treated in this way, but the epidemic of influenza broke out a month earlier than was expected and this invalidated the results Recently, a series of boys on the naval training ship at Shotley were given three subcutaneous injections at two weekly intervals The results were not encouraging, and it may well prove that formolised virus is inactive The possibility of using live virus for prophylactic purposes should be considered

Dr H J Parish (Beckenham) expressed his dissatisfaction with the status of prophylactic measures against diphtheria in this country and pleaded for their more widespread use In discussing the relative merits of the various immunising preparations available, he said that F T (formol toxoid) is apt to give undesirable reactions and is less efficient than A P T (alum precipitated toxoid) and T A F (toxoid-antitoxin floccules) A P T is the most potent antigen but it sometimes produces reactions in older children and in adults in whom T A F might therefore be substituted The latter should certainly be used if there is sensitivity to a detector dose of A.P T T A F contains a little serum and accordingly sometimes causes serum sickness, but the frequency of this occurrence has now been reduced by the use of refined serum which has been concentrated by proteolytic enzymes and so has a lower protein content For high grade immunisation the interval between injections is of more importance than the size of the dose Four weeks should elapse between the first and second injections, but if three injections are given the interval between the second and third need not exceed two weeks Dr Parish believes that the Schick test is of great value in assessing the efficacy of immunisation, but it has the defect of individual variation and a zone of partial immunity separates positive and negative reactions He said that it may be necessary to give periodic injections of T A F or A P T in order to achieve permanent immunity—e g a child may be immunised when he first goes to school and again when 9 years old The Schick test may be omitted if it becomes customary to give reinoculations in this way

SECTION OF PATHOLOGY AND BACTERIOLOGY

Prof. JOHN CRUICKSHANK (Aberdeen) presided over this section, and a discussion on

Non-infective Enlargement of the Lymph-nodes

was opened by Dr JOAN ROSS (London). She described the architecture of the lymph-gland and the character of the cells forming it. According to Maximow a supporting stroma is present in all lymphoid tissue. This stroma consists of a framework of reticulin fibrils, closely connected with which is undifferentiated syncytium. The syncytium is mesenchymal in origin and has the capacity of multiple differentiation. When stimulated the reticular syncytium may give rise to reticulum cells. Specially differentiated reticulum cells called "littoral cells" are found in the various sinuses of the spleen, bone-marrow and liver. There is therefore a common or stem-cell type which when given the appropriate stimulus can differentiate along various lines. In the normal adult the stimulus for the development of the myelocyte is in the bone-marrow and for the lymphocyte in the lymphadenoid tissue. In disease the stimulus may act in an abnormal situation or the stimulus itself may be abnormal. The derivatives of the syncytium, reticulum-cells, lymphocytes of all sizes and histiocytes lie in the meshes. At the edge of the sinuses reticulin fibrils are condensed and some of them cross the lumen of the sinuses and continue into the capsule. These fibres support the littoral cells. The follicles contain few reticulin fibrils, the reticular syncytium forming a supporting stroma for all types of lymphocytes. She thought there is probably a specificity of action by unknown agents on sinus, medulla and follicles causing a hyperplasia of the reticular tissue.

Dr. Ross then went on to illustrate and classify the reticulosis which she defined as a progressive hyperplasia of reticular tissue with differentiation to one or more cell-types. It can be systematised throughout the body or free cellular elements may be present in the blood as in the leukæmias. The three large groups are the medullary, follicular and sinus reticuloses. In medullary reticulosis there are undifferentiated mesenchyme cells in the medullary tissue or in the pulp of lymph-nodes or of the spleen and liver, and possibly in the connective tissues of the body. It may be primary, in which case free cellular elements may appear in the blood, and either hæmic as in the leukæmias, or histiocytic or fibromyeloid as in lymphadenoma. The other group of medullary reticuloses is the metabolic, such as Gaucher's disease and Niemann-Pick disease. In follicular reticulosis there is a hyperplasia of undifferentiated cells in the lymph-follicles and malpighian bodies of the spleen and production of follicular structure in bone-marrow. The types are lymphoid, lymphoid and histiocytic, and giant-cell and fibrillary. In sinus reticulosis there is a hyperplasia of littoral cells in the lymph-sinuses and in the various sinuses of the spleen and bone-marrow. Tissue histiocytes may also be involved.

Dr. A. H. T. ROBB-SMITH (Oxford) dealt with the reticulosarcomata, which include the lymphosarcomas and Ewing's tumour of bone. These are, he said, proliferations of mesenchymal cells or their progeny which result in stromal destruction as well as infiltration. The destruction is best recognised in such organs as the kidney and thyroid. In many cases the reticulosarcomata shows evidence of true embolic metastasis. Little is known of the frequency of these tumours but evidence from the Dutch East Indies suggests that they are more common in native peoples. Of 450 examples of primary lymphadenopathy which he and Dr. Bodley Scott examined 12 per cent. were reticulosarcomas. The greatest incidence is usually between the ages of 50 and 60, but a few arise in young adults. Anatomically there are three groups of reticulosarcomas. The first are those with a primary lesion in an area of lymphoreticular tissue with secondary involvement of the regional lymph-nodes and subsequent metastasis to distant organs by the blood-stream; this is common in the pharyngeal lymphoid ring, the small intestine and the bone-marrow. Secondly, there are reticulosarcomas arising from a pre-existing reticulosis such as lymphoid leukosis or lymphadenoma proper. This association has been emphasised by many writers but Dr. Robb-Smith does not believe that the proportion of patients with reticulosis showing malignant change is any higher than in neuro fibromatosis. The third group are those showing a generalised reticulosarcomatosis analogous to the classical lymphosarcomatosis of Kerndrat. Apart from the second group abnormal cells in the circulating blood are rare.

Dr. Robb-Smith said he had adopted a cytological classification of these tumours similar to that of Gery and Bablet. Showing photomicrographs of the various types he remarked that there are many undifferentiated forms, all the cases described as arising from littoral cells he regards as examples of secondary carcinoma in lymph sinuses. From a clinical point of view it is difficult to give a satisfactory picture because the tumours are protean in character and may arise anywhere in the body. Generally the growth is rapid and painless and interference with function is the first symptom. The lymph-nodes are soft and become moulded into a solid mass. The inguinal nodes are commonly the first to be involved—an unusual position in early Hodgkin's disease; and furthermore the patient is often over 45. There is no doubt that irradiation is the treatment of choice except for tumours of the intestine and bone-marrow where excision followed by irradiation is best. The survival of all cases averages about two years, but some patients are well even after seven years. The speaker concluded by appealing for a centralisation of information about the primary lymphadenopathies, on the lines of the American bone sarcoma registry. Only in this way, he believes, can adequate knowledge be got about the prognosis and best method of treatment for an individual patient.

Dr. W. B. DAVIS (Blackpool) spoke of the experimental aspects of Hodgkin's disease. Among 230 Gordon's tests there were 8 false results, it is important to remember that spasticity and ataxia are the criteria of the positive test-rabbit and that salivation and fits are due to cerebral trauma and not to any agent in the gland. Speaking of his alternative to the Gordon test, which he called "a Friedman test," Dr. Davis said that in his hands it has been considerably more accurate. It has the advantages of being applicable to post-mortem material and to pus. He emphasised that the test does not replace but is only complementary to histological examination. To the criticism that a positive result may be given by normal tissues such as eosinophils he answered that he has obtained a positive Friedman in tissues which had no such cells. There is a possibility of certain reticulum cells playing a part in the reaction and in any case the

test is a biological means of distinguishing a particular type of cell

Dr C E VAN ROOYEN (Edinburgh) agreed on the greater delicacy of the Friedman test He does not now believe in the virus theory of Hodgkin's disease, but thought it would be unwise to bang the door on this explanation till more is known of viruses The disease appears to be neoplastic, since transmission has been impossible Reticulum cells, or certain of them, probably contain the active agent When he exposed Gordon's agent to X-radiation he found it was not inactivated Some of the cells in lymph adenomatous tissue are altered in such a way as to give certain of the biological properties of normal bone marrow Dr van Rooyen noticed a relationship between the prognosis of a case of lymphadenoma and the positivity of the Gordon test It is necessary to remember that the histological picture sometimes changes at different stages of the disease

Dr ROBB SMITH said that often Hodgkin's disease does not give a positive test, but he could not deny that a special type of reticulum cell may be responsible It is important to remember that large numbers of granular leucocytes almost always do give a positive test

Dr ROSS, in reply, pleaded for careful histological examination of all suspected nodes and for better coöperation between pathologist and radiotherapist The Friedman test and sternal puncture will help to correlate different types of disease

Dr R J V PULVERTAFT (London), speaking on sterilisation of dressings and surgical appliances, expressed grave doubts of the efficacy of general hospital sterilisation Often the pressure gauges on autoclaves bear no relation to the temperature, and much of the apparatus is out of date He has isolated *Bacillus sporogenes* and *B tetani* from material alleged to be sterile The too tight packing of drums, and the including of various folded materials, is often responsible for improper sterilisation The finer the texture of a dressing the more difficult it is to sterilise and wood pulp dressings are worst Talc for the surgeons' gloves is another source of infection, and even at full pressure of the steriliser it is almost impossible to kill anaerobes Speaking of the surgeon's mask, he said his tests showed that hæmolytic streptococci may be held up in the layers of the mask during normal breathing but are forcibly expelled in large numbers when the surgeon coughs He concluded with a plea for air conditioning in all theatres and expressed the view that the impregnation of dressings with antiseptics is probably worth while

Prof C H BROWNING, F R S (Glasgow), said that publicity is needed for Dr Pulvertaft's ideas Hospital sterilisation in many cases has degenerated into a ritual—Dr PULVERTAFT, in reply, thought that its chief fault is that it is largely out of the control of the bacteriologist

Dr A C LENDRUM (Glasgow) read an occasional paper on glomangiomas

REVIEWS AND NOTICES OF BOOKS

Sterility and Impaired Fertility

By CEDRIC LANE-ROBERTS, M S Lond, F R C S, F R C O G, gynæcological surgeon to the Royal Northern Hospital, London, ALBERT SHARMAN, M D Glasg M R C O G, assistant surgeon to the Royal Samaritan Hospital for Women, Glasgow, KENNETH WALKER, M B Camb, F R C S, surgeon to the genito-urinary department of the Royal Northern Hospital, and B P WIESNER, D Sc, F R S E, consulting biologist to the Royal Northern Hospital London Hamish Hamilton 1939 Pp 410 14*s*

At a time when the population problem is being widely discussed the appearance of this book is opportune While it is uncertain how much of the nation's reduced fertility is due to an increase in involuntary sterility, it is obvious that, from the demographic standpoint, the question is far from negligible Indeed the establishment of one or more centralised clinics for the diagnosis and treatment of sterility is likely to be a part of any organised population policy which, in coming years, the Government may introduce For such clinics, this volume would be invaluable

Of the many advances which have recently been made in the analysis of sterility, none is more important than the recognition of the part which is played by the male, and the chief of the many merits of this book is that it deals in equal detail with the two sexes The causes of sterility, when systematically reviewed are so numerous and diverse that, to anyone who had not enjoyed a training in biology, it would be a source of astonishment that as many as 85 per cent of marriages are fertile The fact that several specialties—andrology, gynæcology, pathology and endocrinology—have staked out claims on the territory which this book covers imposes the necessity of multiple authorship Yet the volume has none of the shortcomings which are all too familiar in the symposium The different sections are, in the first place, exceptionally well coördinated so that there are neither inconsistencies nor matuses Then the subject matter, which is in parts (particularly those concerned with endocrinology) highly complex, is presented in a logical and carefully planned sequence with a judicious use of headings, subheadings and cross references The literary style is throughout uniformly smooth, terse and clear The whole book bears witness to an unusually strict and meticulous standard of editing The descriptions of the numerous tests in the diagnosis of sterility are supplemented by cautious evaluations of their reliability in the light of our present knowledge

The book deserves to be read by a wide medical public We hope that the authors will keep it up to date by producing revised editions as further relevant information accumulates It is attractively produced with numerous clearly explained tables and illustrations

Nelson New Loose-Leaf Medicine

Renewal pages London Thomas Nelson and Sons 1939

THE latest pages of the Nelson Loose-leaf Medicine make up the deficiencies in the work to which we have previously called attention New articles replace the old on bronchopneumonia, erysipelas metabolism obesity, beri-beri pellagra, diseases of the thyroid gland, Hodgkin's disease, tuberculosis of the lymphatics, bronchoscopy, pulmonary emphysema, and spontaneous pneumothorax, and there is a new article for the "survey volume" on sulfapyridine (M & B 693) These are reasonably uniform in plan, and present modern orthodox views in a straightforward way, with the more important references appended to each article Dr Frederick T Lord gives a detailed account of the bronchopneumonias ranging from the hypostatic type to that associated

with various specific infections, such as tularæmia and plague; perusal of this article strongly supports the impression that the old "anatomical" classification of the pneumonias has outworn its usefulness and should be replaced by one based on ætiology wherever possible In the section on emphysema, Dr. D W. Richards uses the term "obstructive" to describe the common large-lunged emphysema; this is in accordance with current American practice, but implies a theory of ætiology that is not everywhere accepted as operative in all cases The section on diseases of the thyroid, coming from the pen of Dr. J. H. Means, is authoritative, but many readers would have liked more about the heart in thyrotoxicosis Dr. Hans Kjaergaard contributes a brief but informative article on spontaneous pneumothorax, a subject which his own researches have done much to elucidate The present position of sulfapyridine (M & B. 693) is well summarised, but the mention of two isolated reports of the use of the drug in infective endocarditis and in a staphylococcal infection taken alone present an unduly optimistic picture

The Medical Applications of the Short-Wave Current

By WILLIAM BIERMAN, M D, attending physical therapist, Mount Sinai Hospital, New York City; assistant clinical professor of therapeutics, New York University College of Medicine London: Baillière, Tindall and Cox. 1938. Pp. 379. 22*s.* 6*d.*

THE doctor who proposes to apply a new agent in therapy or to extend its use should not only be conversant with the manifestations of the disease to be treated but also have some scientific knowledge of the agent he proposes to employ. Dr Bierman has wisely enlisted the services of a physicist, Myron M Schwarzschild, M.A., who has contributed a valuable section on the physical and technical aspects of high-frequency currents. Beginning with fundamentals, the reader is very gently initiated, step by step, into the secrets of ultra-short waves A good survey of European and American clinical methods is presented with commendable reserve The handbook will be found valuable to any practitioner who is thinking of using this comparatively new physical agency.

The Dream World

A Survey of the History and Mystery of Dreams. By R. L. MÉGROZ. London: John Lane, the Bodley Head. 1939. Pp. 319. 10*s.* 6*d*

DREAMS have always attracted the attention of mankind, and their interpretation has been a function of the learned of all ages To the primitive mind, a dream is a direct message from some force outside the dreamer, and the fear that it may foretell some disaster leaves him uneasy until a satisfactory interpretation has been found This idea dies hard, and we still have our quota of primitive minds in all walks of life today

Mr Megroz has made a serious study of the whole subject, and traces the story of dreams and their significance throughout history He accepts the Freudian conception of dreams but objects to its being so closely bound up with psycho-analytical therapy His examination of the subject has led Mr Megroz to believe that a dream may retell past events unknown to the dreamer, and may in some instances foretell the future He gives examples to illustrate his theories, many of them experiences of well known people Mr Mégroz makes no assertions. He puts forward his views and gives his examples, and is content to leave the reader to make his own deductions.

This book makes interesting reading and provokes thought If the author's adherence to theories which have long been considered outworn also provokes criticism, it should not on that account be too lightly dismissed.

Medical Opinions on War

Issued by the Netherlands Medical Association. Amsterdam: Elsevier Publishing Co. 1939. Pp. 72.

THIS pamphlet is issued in England by the committee for war prophylaxis of the Netherlands medical association and contains short essays by a number of psychiatrists, principally British, Dutch and American Their aim is "to enlarge the self-knowledge of common citizens and politicians. . . (They) do not pretend to any scientific discoveries; they sound the voice of medical common sense" The contributions are of unequal value and in one or two cases hardly merit the title of medical. Amid a wide variety of opinion expressed, there is, however, considerable agreement on the value of studying war from the psychological side Many of the authors draw attention to the importance of unconscious aggression, and the tendency of individuals to behave in groups on a lower cultural plane than they would if alone The relation of aggression to frustration is also frequently touched upon, and the value of reasonableness and compromise in international relations as well as in private affairs is stressed.

Few of the essayists seriously tackle the question of prophylaxis, but those who do recommend a variety of highly controversial courses From this it appears that although psychopathology has already much to contribute towards an understanding of warfare, it is altogether premature to prescribe a preventive regimen.

Chronic Arthritis

By ROBERT T. MONROE, A B, M.D, physician to the Peter Bent Brigham Hospital, and chief of the Medical Staff of the Long Island Hospital, Boston, Massachusetts London: Humphrey Milford, Oxford University Press. 1939 Pp. 84. 8*s.* 6*d*

THIS monograph is reprinted from the Oxford Loose-leaf Medicine and is an admirable exposition. The sections on pathology and ætiology are clear and comprehensive At times brevity is carried almost too far and statements are made which, while probably true, deserve fuller argument, the place of circulatory disturbances in the ætiology of rheumatoid arthritis is dealt with in five lines In conformity with the American usage the terms atrophic and hypertrophic are used instead of rheumatoid and osteo-arthritis, and no attempt is made to differentiate between rheumatoid and infective arthritis as is sometimes done in this country. Periarticular fibrositis is described as a third form and this nomenclature, which has much to commend it, enables the author to include a very useful section. The observations on prognosis in atrophic arthritis and the attitude of the physician deserve to be widely read. Treatment is practical and free from fads and a sound and useful scheme of diet is given

The book bears the stamp of wide personal experience and trained observation, and may be studied with advantage not only by the general practitioner, for whom it is primarily intended, but also by specialists in the subject

THE LANCET

LONDON SATURDAY, SEPTEMBER 9, 1939

TOWN INTO COUNTRY

BEFORE the war, as we must soon be saying, charities planned to send some town children every year for a few days or weeks into the country, and their organisers dreamt of ways and means by which all town children might go Others, more imaginative still, schemed to move out the town hospitals, leaving only enough to deal with emergencies and outpatients This week war has made these dreams come true, and though its later horrors must perhaps inevitably outweigh its early blessings at least it starts with something on the right side The actual mechanism of evacuation, both of children and hospitals, worked smoothly, and, except for some northern towns where the urgency is not so great, the task was finished by the middle of the week Between Friday morning and Sunday night the L C C, acting as the Government's agent, moved out from London half a million school-children, expectant mothers, and blind people, and on Monday these were followed by the younger children with their mothers, and their brothers and sisters of school age who had stayed behind so as to keep families together With the parties went nearly all the council's teaching staff, some 20,000 voluntary helpers to look after the pre school children, and the necessary midwives The blind and the expectant mothers near their time went by motor-coach, the others travelled by rail A quarter of those expected failed to turn up, partly because of holidays and hop picking, and many others came on the spur of the moment Nevertheless, the council were able to make good their promise that if evacuation was ever ordered it would be an orderly operation The hospitals in danger areas divided their patients into three categories those fit to go home, those fit to move but still needing inpatient treatment and those unfit to move Many in the first category were sent home before the week end The second category, the stretcher-cases, were moved out of London on Sunday, mainly by Green Line coach or private car, to the country hospitals that have been enlarged or partially emptied to receive them Only the third category remain Here again there was no major hitch

The complications of evacuation cannot yet be foreseen In the hospitals they seem likely to amount to no more than inconveniences Among the children the risk of infection cannot be denied Children from crowded cities, which may be considered as permanent epidemic centres of the common infectious diseases, are carrying specific organisms into rural districts which may be, but often are not, permanent epidemic areas for those same organisms The result will depend not so much on whence the emigrants came as on where they have gone, and the risk, where there is any, is much less to the evacuees than to those on whom they are billeted The transference from one place to another will not necessarily disturb the epidemic equilibrium provided there is no overcrowding and the two places are in a similar epidemic state Thus, if Portsmouth is evacuated into Bournemouth without overcrowding, Bournemouth has nothing to fear—a comparable migration takes place every year at holiday time and nothing usually happens Where the children are sent to small circumscribed towns such as Ipswich, as Dr A M N PRINGLE, its medical officer of health, has lately pointed out,[1] the effect may be different, for if such a town has been free from any one of the endemic infections for some time the immunity of the residents will be low and the risk of infection correspondingly high A special case is the small community relatively protected from diphtheria by artificial immunisation In some of these districts there are no chronic carriers of diphtheria and the artificially acquired immunity is sufficient to protect the population from diphtheria But if children come to such a district from an epidemic area and include, as they are sure to do, some carriers, diphtheria may spread among the non-immune residents Town children sent to isolated rural districts may then be expected to set up epidemic situations among the native population, severe if there is much increase in the population density, troublesome and lingering if the newcomers are well scattered The risks of diseases not spread by droplets will depend mainly on the state of sanitation, and here again the sparsely populated rural district is the most likely to suffer

Thus, though all reception areas must expect some increase in the number of cases of infectious disease corresponding to the increase in the population at risk, and also some interchange of parasites, it is only in the most rural areas that real trouble is likely to arise, and these must make sure that they are in as good a position as possible to deal with it Preventive measures (which are set out in greater detail on page 618) will include the examination of evacuees for obvious nasopharyngeal infection, systematic immunisation of native children against smallpox and diphtheria, adequate spacing in dormitories and schoolrooms, extra care of drainage systems and milk, food and water supplies, and adequate augmentation of isolation hospital and laboratory facilities and of the public health staff in reception areas With such precautions it is hard to believe that the ills that may befall the natives will seem of any significance when compared with the gain, both in health and experience, of the newcomers

SHOULD LOCAL GOVERNMENT INQUIRY REPORTS BE PUBLISHED?

THE system of public local inquiry is so valuable an instrument of local government administration that it may be worth while to ask whether it operates to the best advantage Recent events at Stirling offer an instance, if not perhaps a very

[1] Pringle A M N., *J R san Inst.* August 1939 p. 71

important one, for examination The Stirling borough council, having decided to remove its medical officer of health, suspended him from office and applied to the Department of Health for Scotland for the requisite statutory consent to his removal The department caused a public inquiry to be held by a commissioner, Mr. CHARLES MACINTOSH, K C, sheriff principal of Argyll, assisted by a medical assessor For some ten days the inquiry ranged over local affairs and personalities in Stirling Finally the commissioner reported to the department which has now informed the town council that the removal of the medical officer is sanctioned But apparently the council itself does not emerge scatheless from the investigation The department asks the council to send a representative delegation to Edinburgh early in September in order to discuss certain questions arising out of the inquiry The council has resolved that its full public-health committee shall represent it in the Edinburgh discussions. But some of the councillors plainly thought that the council was entitled to know in advance the subjects to be dealt with—in other words, to have the chance to prepare itself to answer criticisms, if any, contained in the unpublished report of the commissioner

The purpose of the recent inquiry at Stirling was, of course, strictly limited. The issue was whether or not the department would confirm the dismissal of the medical officer. That issue has been settled But, in the course of settling it, there were naturally complaints of existing arrangements Thus, to take a single instance, a medical witness commented on the system of examining swabs for diphtheria at Stirling "If I send in a swab at 6 P M on Friday," he observed, "it is too late for office hours: the swab is dealt with on Saturday morning and is sent to Glasgow: Glasgow receives it after office hours and deals with it on Monday: you get the result on Tuesday and the funeral is the same day." It is by no means clear that the medical officer was to blame for the system of sending swabs to Glasgow However that may be, the town council itself was in some degree on trial at the inquiry. But, whatever faults were hinted or disclosed, the peculiarities of our so-called administrative law reveal themselves The commissioner hears the evidence and forms his opinions thereon; yet he is not the judge who makes the decision Somewhere behind the scenes an anonymous official in the department studies the commissioner's unpublished report and eventually, after the file has been circulated to appropriate colleagues, the impersonal judgment is promulgated. The outgoing medical officer of health has not seen his judge face to face. The town council does not know what charges are being levelled at its administration No official report of the case will appear. There will be no statement of reasons for the departmental decision such as would help Scottish local authorities in similar positions another time

These comments are not intended to suggest that there is anything improper about our system of local government inquiries The inquiry is not a criminal trial. Local feelings have been usefully ventilated The citizens in Stirling and elsewhere are in consequence able to feel that no scandal is being hushed up Indeed the system of such inquiries was justified after a strong legal challenge in Local Government Board *v* Arlidge in 1915 The House of Lords then upheld the departmental method, incidentally correcting the Court of Appeal wherein the judges by a majority decision had said that the method was contrary to "natural justice" Nobody can doubt that the best way to remove any possible deficiencies in public-health administration in Stirling is for the public-health committee to discuss matters with the central department. Nevertheless there remains the question whether our central authorities' control is not at times a little too mysterious and secretive The Arlidge case concerned a property-owner's objection to a closing order for a house in Hampstead alleged not to be fit for human habitation It was therefore quite different from the issue in the Stirling case But there is one feature common to both occasions—the non-publication of the report of the person holding the inquiry. The late Lord SUMNER made some characteristic observations in the Arlidge case which the Committee on Ministers' Powers thought worth quoting in its report in 1932 "If it was our function," he said, "to advise the Local Government Board as to its procedure generally . . . I should for my part suggest that the more open the procedure is the better By all means let both the appellant and the local authority see the inspector's reports; a discreet and careful officer is not likely to offend, and if, in spite of discretion and care, he is harassed by actions for libel, he may well be defended and indemnified by his department By all means let the appellant, and the local authority too, if it wishes, see and address the judge: it is all in his day's work. By all means let the appellant have the last word and as many of them in reason as he likes. Time spent in removing a grievance, or in avoiding the sense of it, is time well spent; the Board's officials will, like good judges, amplify their jurisdiction by rooting it in the public confidence."

ŒSTRONE AND PROGESTERONE IN THE ADRENAL GLAND

SINCE GORDON HOLMES gave his now classical description of virilism in a woman cured by the removal of an adrenal tumour, several similar cases have been reported, and it is now well established that overgrowth of the adrenal cortex may lead to masculinisation of the secondary sexual characters and to retrogressive changes in the internal reproductive organs. Complementary observations have been made on analogous, but much rarer, cases in which a partial feminisation of men has occurred from a similar cause [1]

For many years no satisfactory advance was made in the analysis of this peculiar relationship between the adrenal cortex and the sex characters, but lately advance has come from three sides The importance of the adrenal cortex in the body's

1 Simpson, S L, and Joll, C A, *Endocrinology*, 1938, 22, 50

economy has led to much work on the identification and preparation of the life-maintaining principles of the cortex, which prove to be of very similar chemical constitution to the hormones of the gonads[2] Secondly, examination of the urine in cases of adrenal tumours and adrenal hyperplasia, associated with masculinisation or feminisation, has shown that this is one of the few conditions, other than pregnancy, in which an easily detectable abnormality can be found in the hormonal activity of the urine An excess of androgenic material is associated with masculinising tumours in women[3 4] and an excess of œstrogenic substances with feminising tumours in men[5] The excess androgenic activity seems to be largely accounted for by the presence of massive amounts of *trans* dehydroandrosterone, but as this substance is a very weak androgen it is perhaps only an excretion product of the androgenic substance primarily responsible for the masculinisation The additional œstrogen in the urine of males with adrenal tumours has not been identified with certainty, but is probably œstrone An extragonadal source of sex steroids is also implied by another observation made in the course of hormone analysis of body fluids—i e, that gonadectomy does not cause the disappearance of androgens and œstrogens from the urine—and of possible sources the adrenal gland is much the most probable[6]

The third line of approach consists in the examination of cortical tissue itself for the presence of substances identical with, or of similar biological activity to, the well known hormones of the ovary and testis The first success in this direction was attained in 1936 by REICHSTEIN, who isolated from adrenocortical extracts a substance, "adrenosterone," which had definite androgenic properties as tested on the capon comb, and which differed from well known members of the androsterone-testosterone series only in having an extra oxygen group in the molecule His discovery indicated that substances with sex hormone activity are present in the cortex, although the particular substance adrenosterone, being a weak androgen, is perhaps unlikely to be responsible for the major phenomena of virilism in women In the past year, two observations have been made which definitely link the adrenal gland metabolically and perhaps endocrinologically with the gonads BEALL and REICHSTEIN[7] and BEALL[8] have isolated, from concentrates of very large amounts of ox adrenals, a substance identical chemically and biologically with the hormone of the corpus luteum, progesterone, which previously had been obtained only from the corpus luteum itself Very recently BEALL[9] has also obtained from adrenal extracts œstrone in crystalline form identical with the substance found in human pregnancy urine The latter observation is especially striking since œstrone has not yet been isolated in pure form from the ovary, and BEALL's isolation of it from the adrenal cortex is its first preparation in pure form from any kind of tissue

These three lines of work point quite definitely to the fact that the adrenal gland normally contains—probably as the result of elaboration there—small amounts of substances identical with or similar to the hormones of the gonads, and that under certain conditions of hyperplasia or malignant growth the output of these or similar substances can so be augmented that the sex characters of the subject are fundamentally altered It is impossible with our present somewhat limited knowledge of the metabolism of the steroid substances to postulate whether this anomalous presence of biologically active substances in the cortex is incidental to the large scale production of the chemically similar life maintaining hormones, or whether they are produced by the cortex independent of the elaboration of corticosterone In this connexion, of course, a study of the sex steroids present in the cortex or excreted in the urine in cases of known deficiency of the life-maintaining principles, as found in Addison's disease, would be instructive, but progress of this kind is necessarily slow Moreover, it should be emphasised that the observations on the urine in cases of adrenal hyperplasia and adrenal tumours, as well as of the physiological effects of these conditions, have all been on the human subject, whereas the large scale examination of adrenal extracts has necessarily been carried out on animal material It seems likely, however, that this separation will not be permanent DAVIDSON and MOON[10] have shown, for instance, that the artificial stimulation of the adrenal cortex by the administration of corticotrophic extract of the anterior pituitary may cause some restoration of the atrophic accessory sex organs of gonadectomised male or female rats Conversely, the development of microchemical methods will probably make possible the chemical examination of hyperplastic or tumourous adrenals, or even of the normal gland

The International Hospital Association Congress at Toronto arranged for this month has been postponed indefinitely

The annual conference of the Sanitary Inspectors' Association, which was to have been held at Bournemouth this week has been postponed

The Tavistock Clinic (for functional nervous disorders) has now been transferred to the Orchard Wing Westfield College Kidderpore Avenue Hampstead, N W 3 (Tel Hampstead 1626) near the junction of Finchley Road and Platt's Lane In addition to the usual work of the Clinic private practice on a pooled basis is being carried on by a large resident staff Appointments for both Clinic and private patients will be made by the Secretary at any time

The Lancet will for the present be printed at Aylesbury and urgent communications may be addressed to the editor at Messrs Hazell, Watson & Viney's printing works there The London office remains open at 7, Adam Street, W C 2 (Tel Temple Bar 7228 9)

ANNOTATIONS

DRUGS IN WAR-TIME

THE outbreak of war finds this country in a far better state as regards supplies of essential drugs than was the case in August, 1914. Under the protection of the Safeguarding of Industries Act the manufacture of medicinal chemicals and synthetic products has become a staple industry of Great Britain and there is no need to fear a shortage of such articles. The raw materials of this industry are available in sufficient quantity to ensure that the large existing stocks of the finished products can be replaced as need arises. No likelihood of substantial advances in the prices of drugs in this category can be foreseen at the moment and certainly no famine in them is conceivable. At all times, however, it is desirable that care should be taken to conserve stocks and to avoid waste and at no time should the rules of economy be observed more rigorously than in time of war. Many important drugs are brought to this country by sea and a number of others require for their production raw materials which also have to be imported. Thus this country depends for its supplies of the vast majority of the items of vegetable materia medica upon outside sources; similarly our requirements in the way of metals, mercury, and bismuth have to be derived from abroad and the same applies to bromine and iodine. While then Great Britain is self-supporting so far as its needs for the coal-tar derivatives used in medicine are concerned, there may later be occasion for economy in some other categories. Substantial stocks of mercurials, bismuth salts, bromides, and iodides are, we have no doubt, held in reserve while our supplies of the primary products from which they are manufactured will be controlled by the Government. Of the alkaloids, quinine, morphine, and codeine are prescribed more frequently in war-time than in normal times; all three are derived from vegetable raw materials brought here from other countries. It may be assumed that there are considerable reserves of these alkaloids as well as of cinchona bark and opium, and that, if necessary, steps will be taken to prevent any improper hoarding of stocks. Under the defence regulations the Government has power to require any person to furnish an estimate of the quantity of any substance held by him and to requisition all or any quantity of any article so held. It would be difficult to estimate the total quantities of any one of the many hundreds of vegetable drugs used in medicine, whether as powder, extract, tincture, or some other kind of galenical preparation. Apart from the stocks in bonded and other warehouses and in the premises of dealers, manufacturing druggists and wholesale houses there are some sixteen thousand chemists' shops and many thousands of other stores among which stocks are distributed. Should a temporary scarcity of any such drug arise as time passes the fact will be made known to members of the medical profession so that they will have an opportunity to adjust their prescribing.

FAMILIAL ADENOMATOSIS

MANY interesting and important facts about familial adenomatosis of the colon and rectum, or polyposis intestini, are set out in the paper by Lockhart-Mummery and Cuthbert Dukes on p. 586. The genealogical tables of ten families afflicted with this disease show clearly its hereditary nature. It may be transmitted by either sex, and is apparently due to a gene defect, which is responsible for an unduly active growth of the intestinal mucosa, followed by the formation of areas of hyperplasia, and later multiple adenomata. The active mitosis which is inevitably present helps to explain the development of carcinoma as a secondary phenomenon. It is shown that adenomata develop at about the age of 20 years, while malignant changes follow in the decade 30–40 or even earlier, hence polyposis should be suspected whenever a young subject is found to be suffering from cancer of the rectum. More than one focus of carcinoma is frequently present. A recent paper by Coffey and Bargen[1] also stresses the liability to malignancy; they found carcinomatous changes in 62·5 per cent. of cases of true adenomatosis (as distinct from the pseudo-polyposis associated with chronic ulcerative colitis), and in 25 per cent. there were multiple carcinomas. A useful clinical point mentioned by Lockhart-Mummery and Dukes is that polypi which are actively growing are darker in colour (dark red or brown) and firmer in consistence than quiescent growths. Coffey and Bargen also say of carcinomatous polyps that they presented "a dusky red hemorrhagic appearance which immediately aroused a suspicion of their malignant nature." The treatment of polyposis is a difficult problem, there is at present no known method of preventing the development of polypi. Since members of these families are faced with the grim prospect of years of medical supervision, with multiple sessions for sigmoidoscopy and fulguration of polypi, finally culminating at an early age in colectomy or radical excision of the rectum and pelvic colon for malignant disease, one may hope that polyposis families will remain small and finally die out as the result of celibacy or the adoption of eugenic principles. Married persons found to be suffering from polyposis should certainly be informed of the familial nature of the disease.

TREATMENT OF BURNS

THE weakness of tannic acid in the treatment of burns lies in its comparatively poor antiseptic action; the eschar fauly often gets infected, and the burn can then no longer be treated as a dry wound. In gentian violet a substance has been found that is non-irritant, strongly bactericidal and analgesic, but unfortunately it is a poor coagulant of devitalised proteins, and the eschar takes a long time to form. Its bactericidal action, according to Chen,[2] is exhibited mostly against bacteria of the gram-positive groups, and hardly at all against *Bacillus coli* or *B. pyocyaneus*. Chen in Peiping and Blackfield and Goldman[3] in San Francisco have been trying to evolve a technique that will combine adequate coagulation with efficient antisepsis. The American surgeons, who have worked mainly with severe burns in children, first immerse the patient in a tannic-acid bath in which ointments and the like, blebs and loose necrotic tissue are removed. Then, after drying the patient with sterile towels, they apply gauze soaked in 10 per cent. silver nitrate to the burnt area; this effectively seals the area before it has a chance of being infected. The patient is next placed on a sterile sheet under a large cradle kept at 85°–90° F. For the first few days the entire burnt area, including its edges, is treated several times a day with a 1 per cent. aqueous solution

2 Chen, C. Y. *Chin. med. J.* 1939, 55, 407.
3 Blackfield, H. M., and Goldman, L., *J. Amer. med. Ass.* 1939, 112, 2236.

of gentian violet Chen's experience has been mostly with the less extensive type of burn, only five of his patients were bad enough to be admitted to hospital He does not use tannic acid but first cleans the burn with boric-acid solution or normal saline removing oily dressings, if they have been applied, with soap, blisters are opened and loose epidermis cleared away He then applies a 1 per cent aqueous solution of gentian violet (crystal form) to the affected area, and after an interval of five to ten minutes applies the silver-nitrate solution The gentian violet is reapplied two or three times at fifteen minute intervals, and when the surface has been exposed to the air for two hours the patient is allowed to go home No direct dressings are applied after the first treatment, the burns being either left uncovered or guarded by iron wire screens covered with dry gauze The dye is reapplied once or twice on the second day, and the wounds are then covered with a dry dressing which is removed for inspection daily for the first two to three days, and after that only every four days In cases known to be infected with *B coli* Chen replaces the gentian violet by a mixture of gentian violet, acri flavine and brilliant green He says that only the first dressing is painful, and healing is very prompt The eschar formed with gentian violet is pliant and does not crack in the body folds or at the edges, but its removal is not always easy Chen recommends saline compresses to loosen the parts of the eschar that have not peeled off at the end of three or four weeks, but Blackfield and Goldman have not been satisfied with this method They hold that any eschar remaining after this period covers third- or deep second degree burns and that if it is merely soaked off epithelisation will not take place They favour surgical removal of the eschar under light general anæsthesia, and preparation of the resulting raw area for skin grafting

PITFALLS IN INJECTING FOR HERNIA

REPORTS on the injection of sclerosing solutions for the cure of hernia usually make little mention of the unpleasant results that may follow possible accidents Perhaps most of these reports are written by the specially skilled at whose hands accidents do not happen Wernicke[1] however feels it necessary to emphasise the fact that injecting a hernia is not a simple matter like giving a hypodermic injection The two most serious calamities which can occur are injection into the peritoneal cavity and injection into the deep epigastric vessels Wernicke quotes two deaths, reported by another writer, in which the solution was injected into the bowel wall with resulting gangrene perforation and peritonitis, he adds that it is quite wrong to think that intraperitoneal injection is not of serious consequence Injection into the deep epigastric artery may be followed by sloughing of the deep tissues The obvious safe guard is to withdraw the plunger a little way before starting the injection All patients who experience severe abdominal pain after injection should be treated as potential cases of peritonitis and kept under careful observation

Œdema of the cord, hydrocele of the cord epididymitis and dermatitis under the truss worn during treatment all seem to be of minor significance but it is as well to recognise that they may occur Abscess formation may be troublesome and does occasionally arise even in skilled hands Harris and White[2] report a series of 236 cases treated by injection with out a single serious complication No abscesses occurred and no impotence resulted They consider that there is little difference in the fibrosis produced by the two types of solution in popular use—those containing tannic acid in alcohol and those containing a fatty acid basis It is perhaps as well to mention that the solutions in use for the injection treatment of varicose veins are not suitable Wernicke believes, as a result of experimental work, that phenol alcohol-thuja solution gives the most enduring scar tissue

It is rather disappointing that these authors fail to restrict the injection treatment to the small indirect inguinal hernia in healthy patients, in fact to the cases which most certainly give good results from operation Harris and White have taken great pains to analyse their results and compare them with results of operation The analysis is in favour of operation It has at times been urged that treatment by injection saves the patient time and money Thus Harris and White are inclined to doubt, the prolongation of the treatment and the number of visits entailed cause great inconvenience Wernicke thinks that 10 injections should suffice for most cases, and that when 20 or 40 are required the case has been badly chosen He gives a good practical tip to prevent the formation of subcutaneous nodules The syringe should contain a little air above the solution, and, after the injection, this air is forced through to clean the needle before its withdrawal

TETANUS ANTITOXIN

SOME confusion may still exist owing to the two units employed for expressing dosage of tetanus antitoxin The international unit (I U), adopted by the Permanent Commission on Biological Standardisation, is now used in this and many other countries, whereas the American unit (A U) is still employed in the United States and elsewhere The relation between A U and I U is 1 2 The routine prophylactic dose at the beginning of the last war was 500 A.U, and there was a tendency later to increase this to 1000 or even 1500 A.U The memorandum issued by the Director General of Emergency Medical Services last week (see *Lancet*, Sept 2, 1939, p 578) recommends a prophylactic dose of about 2600 I U, equivalent to about 1300 A.U, or some two and a half times the old routine dose

OXYGEN AND THE BRAIN

ALTERATIONS in brain metabolism—mainly and essentially a matter of the burning of dextrose—occur in the new "shock" treatments of schizophrenia, and many attempts have been made to find in them the effectual happening common to all these therapies Some have assumed that cerebral anoxia is the answer[1] Russell Fraser and Reitmann[2] in this country, and Himwich[3] and his associates in the United States, have turned this interpretation to practical account by causing in schizophrenic patients temporary acute anoxia by the inhalation of nitrogen The therapeutic value of the method is doubtful, but the significance of cerebral anoxia remains an urgent question Gerard[4] who has lately reviewed the whole topic would attribute the effect of thyroid treatment in schizophrenia to its power of increasing the rate of respiration and the use of sugar in the brain, he regards the low basal metabolic rate and the relative insensitiveness to thyroid of one group of schizophrenics as prima facie evidence of lowered brain

1 See *Lancet* 1938 1 37 210
2 Fraser R. G. *Neurol Psychiat.* 1939
3 Himwich H. E., Alexander L. & D. and Lipets B. *Proc exp Biol Med.*, N. Y. 1938, 39, 26
4 Gerard R. W. *Arch Neurol Psychiat*, Chicago 1938, 42, 93

metabolism He suggests that as the cortical brain potentials are increased in rate and amplitude after acute anoxia, there is neuronic stimulation either during the early stages of decreased oxidation or "on the rebound" after it; hypoglycæmia acts much like *hypoxia on the function of the brain, leading to this secondary "overshooting"* with increased activity which may be the basis of the therapeutic action Gerard would attribute the improvement in the schizophrenic to the increase in the respiration of his brain which may be so caused, and points to the findings of Kerr and of Ghantus[5] that the neurological complications of hypoglycæmia correspond less to the hypoglycæmia in the blood than to the glycogen content in the brain

That there are difficulties in the way of *accepting* cerebral anoxia as the common feature in Cardiazol, insulin and other physical methods of treating schizophrenia may be seen from the study by Stone[6] of the effect of various drugs upon the lactic-acid content of the brain in mice. These small animals were chosen because they could be plunged into liquid air and frozen instantaneously without the anæsthetics and surgical procedures, or the post-mortem changes, which would interfere with accurate estimation Stone found that during insulin convulsions the amount of lactic acid in the brain is significantly decreased, and that a similar decrease sometimes takes place during severe insulin hypoglycæmia without convulsions; a decrease also occurs during anæsthesia. If convulsions are induced with cardiazol, however, the lactic-acid value in the brain remains normal or is significantly increased; picrotoxin produces an increase, too, above the level that can be attained in normal mice after strenuous exercise, and in cyanide convulsions the increase is large. But during nicotine convulsions there is no significant alteration in the amount of lactic acid in the brain

These striking differences between the effects of common convulsants and those of anæsthetics or hypoglycæmia deserve attention Although the mechanism of glucose katabolism in the brain is still obscure, certainly an alteration in lactic-acid content in one direction is not easily made compatible with the view that much the same disturbance of oxidative activity in the brain is taking place then as when the lactic-acid change is in the opposite direction. Stone's findings also run counter to Quastel's[7] hypothesis that the anæsthetic action of drugs—as employed in the continuous narcosis method of treatment of psychoses—is due to specific inhibition of some part of an enzyme system concerned in the oxidation of carbohydrate products, such as lactate; if that were so, one would expect an increased lactate content during anæsthesia, whereas Stone found it to be lowered

Stone discusses various hypotheses to account for his observations, such as that the lactic-acid content is dependent on the activity of the tissue, being highest during convulsions, or that analeptics inhibit some part of an enzyme system, as in Quastel's explanation of the action of anæsthetics, but the readings obtained for nicotine convulsions are not consonant with either of these hypotheses Since, moreover, normal or low readings for lactic acid in the brain were obtained in conditions, such as ether anæsthesia and insulin convulsions, in which there is a high proportion of lactic acid in the blood, it is presumably not from the blood that the extra lactic acid in the brain during picrotoxin or cardiazol convulsions is derived. Stone mentions the possibility that in the latter two conditions the high values may be due to circulatory disturbances resulting in cerebral anoxæmia this would leave unexplained the readings in hypoglycæmia It is evident that cerebral metabolism is a field for active research in psychiatry as well as in physiology.

SURGERY OF GALL-BLADDER AND BILE-DUCTS

THE history of the surgery of an organ is not only of interest in itself, but in addition it frequently conveys valuable lessons which, by analogy, can be applied in other directions With this in mind, Prof Grey Turner opened his Lettsomian lectures[1] on the surgery of the gall-bladder and bile-ducts with a survey of the history of the subject The later phases in the development of the surgery of the bile-passages are made particularly interesting by the author's personal knowledge of many of the pioneers With an experience of 1040 operations on the gall-bladder and bile-ducts to his credit, Grey Turner's opinions *necessarily carry much weight. Having lived and operated throughout the period of the great "cholecystectomy versus cholecystostomy" controversy, such an experienced operator still has occasion sometimes to employ the latter operation.* His warning quotation from a friend that "a living problem is better than a dead certainty" might well be taken to heart by the type of surgeon who sets out to remove the gall-bladder at all costs, and whose skill is sometimes no better than his judgment

It is a surprise to find Professor Turner stating that in his experience cholecystitis apart from gall-stones is an uncommon disease in this country It is not clear with what diagnosis he would label the large number of patients with flatulent dyspepsia, tender gall-bladder, positive cholecystographic evidence, and possibly infection of bile taken from the duodenum. There is still considerable controversy as to whether the acutely inflamed gall-bladder should be operated on as a matter of urgency or should be allowed, if it will, to subside before operation is undertaken. Professor Turner is on the side of early operation, but advocates simple drainage in preference to removal His reasons are the added risks of bleeding, the increased danger of injury to the ducts and the possibility of later sclerosis of the common duct, if cholecystectomy is carried out in the presence of acute inflammatory changes It is a compliment to the sound judgment and careful presentation of facts in these lectures, that one regrets what is not there. In particular we should have welcomed the author's views on the many pathological and clinical problems associated with cholesterosis, but on this matter he has contented himself with a brief reference to the uncertainty of the results of cholecystectomy for "strawberry gall-bladder."

A 'France" pension of £30 per annum will be filled shortly by the council of Epsom College Candidates must be fully qualified medical men of not less than 55 years of age, whose income, independently of any allowance from the Royal Medical Benevolent Fund, does not exceed £100 a year, if single, and £150 if married Two or more St Anne's scholars will also be elected by the council. Candidates must be fully 9 years of age, and must be orphan daughters of medical men who have been in independent practice in England or Wales for not less than 5 years The value of each scholarship is dependent upon the means of the applicant and the locality and fees of the school selected Forms of application for the pension and scholarships may be had from the secretary of the college, 40 Bedford Square, London, W.C.1, and must be completed and returned by Oct 15

SPECIAL ARTICLES

ADMINISTRATION OF FLUIDS TO SURGICAL PATIENTS*

BY F AVERY JONES, M D, M R C P
SECOND ASSISTANT, MEDICAL PROFESSORIAL UNIT, ST BARTHOLOMEW'S HOSPITAL, AND

C NAUNTON MORGAN, M B, F R C S
ASSISTANT DIRECTOR, SURGICAL PROFESSORIAL UNIT AT THE HOSPITAL

IN order to formulate simple rules for the administration of fluids and sodium chloride, intravenously or per rectum, a study of the problems of fluid balance has been carried out in the wards of the surgical professorial unit at St Bartholomew's Hospital during the past three years It has been found possible to eliminate entirely postoperative dehydration and œdema, even with such complications as intestinal obstruction, or paralytic ileus, and the increased comfort and smooth convalescence of all patients requiring parenteral fluids has been particularly gratifying

It must be emphasised that fluids are always given by mouth after surgical operations unless there are *contra indications If, owing to nausea or post-operative vomiting,* adequate oral intake is not possible, this is supplemented by fluids given per rectum, or occasionally, intravenously After all operations on the gut, fluids by mouth are withheld for 24–48 hours or longer This routine diminishes the incidence of postoperative distension and paralytic ileus and may limit the spread of infection in the peritoneal cavity In such cases the method of choice is the administration of fluids per rectum, but this is inadvisable after operations on the rectum or distal colon and intravenous therapy is then required

Much has been learnt in recent years about the normal water balance of the body, and its application to *surgical patients* is due largely to Coller and Maddock (1934–37) who demonstrated the quantity of fluids required by patients after operation, and for the control of *dehydration* They have shown that a sick surgical patient requires at least 3600 c cm of fluid a day

The fluid-loss of a normal person is approximately as follows (Starling 1936)

Urine	1500 c cm
Skin	600 c cm
Lungs	400 c cm
Fæces	100 c cm
	2600 c cm

It is not sufficiently realised that a normal person loses nearly 1000 c cm of water daily by *insensible* perspiration from the skin and as water vapour with expired air There is commonly profuse sweating during and after a general anæsthetic or a prolonged operation, which greatly increases the fluid loss There is no record of this normal fluid loss on the temperature chart and it is commonly overlooked On no account must the urine output be considered as a true index of the water loss of the body for the skin and lungs sometimes (diarrhœa and vomiting) tissues (œdema) all have first call on the available water With the water that remains, the kidneys must excrete the waste products of the body amounting to about 35 g a day Even when the kidneys are concentrating urine to a specific gravity of 1032 500 c cm of water is needed (Lashmet and Newburgh 1937) A damaged kidney able to concentrate only to 1010 will need 1500 c cm to excrete the normal waste products, and if this is not available nitrogenous retention will occur

To allow for the increased loss of fluid by sweating a patient should receive at least 3600 c cm of fluids in the 24 hours after a major operation On the following days 3000 c cm is usually sufficient It may be thought that such a fluid intake is never achieved by healthy people, but it must be remembered that the water contents of solid foods contribute over 800 c cm and the water of oxidation a further 350 c cm

In the past many patients have been fortunate if they have received half this quantity, and a negative fluid-balance was inevitable Even moderate restriction of fluid is *badly borne by healthy people, and* much more so by patients who have had a major surgical operation Although morphia may allay *much discomfort, dehydration, with its many risks* is a serious burden for a critically ill patient, and must materially affect the prognosis

Not only have many patients received too little fluid, but they have often been given too much salt The basic need of the body is only 1–2 grammes a day (Falconer and Lyall 1937) and a normal diet may contain 5–10 g, but 5 g is probably a sufficient allowance If a surgical patient is given his correct postoperative fluid allowance (3600 c cm) as isotonic normal saline, he will receive as much as 32 g in the 24 hours, and may have difficulty in excreting this amount This has been shown by determining the chloride excretion in the urine (Avery *Jones and Naunton Morgan 1938)* It was shown by Baird and Haldane (1922) that 35–40 g of sodium chloride taken in a day by a healthy man caused visible œdema *The sodium chloride retains* water in the tissues, and there may be an increase in blood-volume as shown by a fall in the hæmoglobin percentage The associated fall in *plasma proteins* is dangerous, for this facilitates the retention of water in the tissues and the production of œdema, which may hinder the healing of wounds or may waterlog the lungs These risks have been emphasised by Maddock and Coller (1934), Mauzels and Smith (1934), Walther (1937) Falconer and Lyall (1937), and Bartlett, Bingham and Pedersen (1938)

The *regime recommended is to give dilute saline* so that the uncomplicated case will receive about 5 g of sodium chloride a day When giving rectal fluids, one volume of normal saline to four volumes of tap water is used , for intravenous injection, one volume of normal saline to four volumes of 5 per cent (isotonic) glucose in distilled water

In addition to this basic allowance of fluid, extra normal saline is given to cover exactly any loss of intestinal fluid or blood If the patient has vomited 1000 c cm then he is given 1000 c cm of normal saline in addition to his daily allowance of dilute saline This principle of replacing lost intestinal fluid by normal saline has also recently been advocated by Bartlett, Bingham and Pedersen (1938) who also have found it successful

SOLUTIONS USED

0 18 per cent sodium chloride (one part of normal saline to four parts of tap water) —This solution is given per rectum as a continuous drip (60 drops per minute, using a No 6 rubber catheter) and it is usually

* Based on a full report published in *St Bartholomew's Hospital Reports* 1938

retained very well It is uncommon to give less than 3000 c cm. in twenty-four hours, and we have given as much as 6000 c cm

4 per cent. glucose, 0 18 per cent sodium chloride (one part of normal saline to four parts of 5 per cent glucose in distilled water) —This solution is isotonic and is given intravenously as a continuous drip. At the rate of 3000 c cm a day, it supplies 120 g. of glucose and 5·4 g of sodium chloride The tendency to thrombosis of the vein is perhaps greater than with normal saline; it is usually necessary to change the vein after forty-eight hours, but the same vein has been used for as long as five days. The solution may be given per rectum, but we have found that it is not so well retained as the saline diluted with tap water

0 9 per cent. sodium chloride (normal saline). —This solution may be given intravenously, but it is not as well retained when given per rectum as 1/5 normal saline Its indications are:

1. Volume for volume to replace any lost intestinal fluid
2. To replace blood loss, if a blood transfusion is not given.
3. To be given if there is severe shock, while waiting for a blood transfusion.

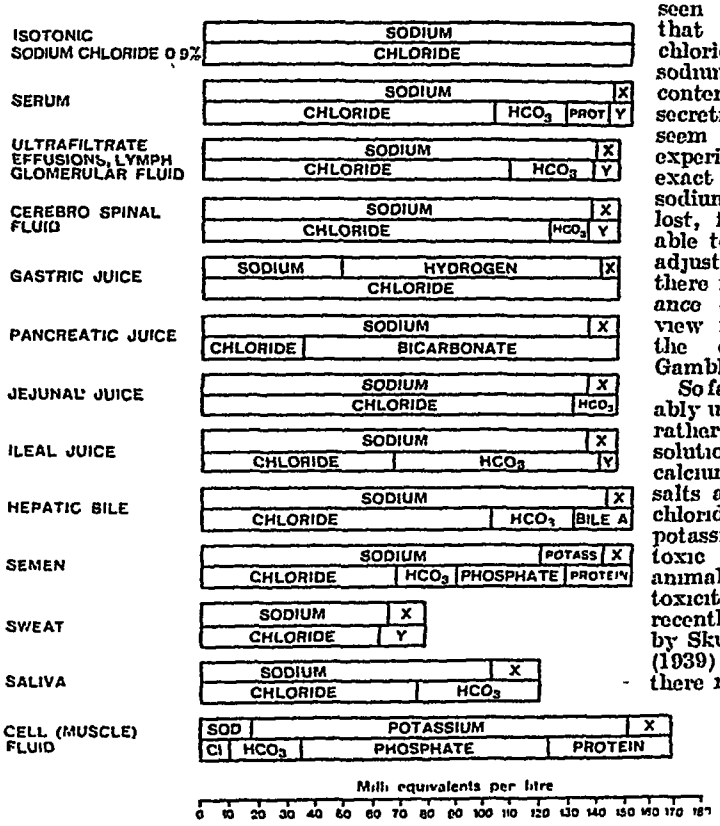
Hypertonic saline has a limited application, for in surgical patients there is never loss of salt without loss of water Both can be replaced by normal saline. Hypertonic saline, however, is of value in cases of established paralytic ileus, where there may be considerable stagnation of fluid in the dilated loops of intestine Three hundred c cm. of 5 per cent sodium chloride may be given in order to reverse the flow of secretions and return fluid from the gut into the blood

It will be observed that we do not use the common 5 per cent dextrose in normal saline This is hypertonic, and contains too much salt for routine use It must be added that whenever possible, intestinal secretions should be returned to the intestine—e g bile from a fistula, or from drainage of gall-bladder, should be returned to the stomach through a Ryle's tube or nasal catheter

Using these simple rules during the past two years, it has been found possible to keep the blood chemistry practically within normal limits, even when there has been continuous gastric drainage for as long as nine days The patients have not shown evidence of dehydration, and have not suffered from thirst

Male aged 46 —Partial gastrectomy for gastric ulceration. He vomited 1000 c cm. the third day after operation. A Ryle's tube was passed into the stomach and continuous suction begun with a Wangensteen apparatus. A few days later the drainage was stopped, but vomiting recurred and radiography showed a much dilated duodenal loop and barium did not pass into the jejunum. An entero-anastomosis was performed and convalescence was subsequently uninterrupted.

Aspirated gastric contents, or vomitus, may contain as much as or more sodium than is present in blood. Bartlett (1938) and his co-workers found an average concentration of 5 7 g. of sodium chloride per litre in one hundred 24-hour specimens of gastroduodenal drainage Since sodium is the main base of the extracellular fluids, when it is lost from the body, there must be a reduction in the volume of these fluids This dehydration cannot be repaired by water alone, for this could not be retained in the tissues without profoundly upsetting the osmotic pressure. Sodium must be given in addition. It will be seen from the table that isotonic sodium chloride will cover the sodium and chloride content of any intestinal secretion. It does not seem necessary in our experience to give the exact proportions of sodium and chloride lost, for the body is able to make its own adjustments provided there is a liberal allowance of water. This view is confirmed by the observations of Gamble (1929).



Composition of the body fluids.
X = unnamed basic radicles Y = unnamed acid radicles
(After R. A. McCance, Lancet, 1936, 1, 704)

So far we have invariably used normal saline rather than Ringer's solution, which contains calcium and potassium salts as well as sodium chloride Intravenous potassium is extremely toxic in experimental animals and its possible toxicity in man has recently been reviewed by Skudder and others (1939) In any case there may be a moderate allowance of potassium from the body proteins which are broken down when intravenous or rectal fluids are given, for it is impossible to give proteins by these routes. Again, the stores of calcium in the body are so large and labile that it hardly seems necessary for a few days to add the small amount in Ringer's solution. These are, however, theoretical points, and there seems scope for further biochemical investigation Using isotonic glucose and isotonic saline in varying proportions has the advantage of simplicity.

It should be noted however that Falconer (1939) has reported favourably on the use of Ringer's solution in established cases of dehydration, and its use has also been advocated by Graham (1937).

Intravenous therapy is at present a very incomplete diet, and should not be continued longer than absolutely necessary.

MANAGEMENT OF CASES COMPLICATED BY ABNORMAL FLUID LOSS

It is essential to record the fluid intake and loss on the temperature chart, so that the fluid balance can be seen at a glance Daily estimation of the

Days	1 Op	2	3	4	5	6	7	8	9	10 Op	11	12	13	14	15
Fluid intake—															
By mouth			450	2040		420		970	990			465	1440		
Per rectum															
N/5 saline	3000	3000	1000												
N saline				1500											
Intravenously															
4 per cent. dextrose in 0·18 per cent NaCl					2000	2150	2500	2500	1500	3200	3000	3300	2000		
N saline					650	400	1450	550	1030						
Fluid loss—															
Vomit				1600					450						
Gastric drainage					550	500	1350	600	690						
Urine		700	1500	2350	1000	700	750	1150	1350	450	850	1350	1300		
Blood—															
Blood urea mg per 100 c cm			35			54		40		32		47		25	
Alkali reserve Vols CO_2 per 100 c cm			58 7			60 4		67 0		61 7		55 5		60 4	
Plasma chlorides mg NaCl per 100 c cm			588			611		595		597		559		582	

Op = Operation

haemoglobin percentage is of great value in all difficult cases If there is concentration of the blood as with dehydration, the haemoglobin will rise, if there is hydraemia due to retention of excess sodium chloride, there will be a corresponding fall in the percentage of haemoglobin Of course blood lost at the operation will cause a fall at the rate of 12 per cent for every 600 c cm of blood

The simplest test on the urine is for chlorides If absent, the intake of sodium chloride may be increased, but this is seldom necessary on this regime If a patient is having an adequate intake of sodium chloride a sudden decrease in the output of chloride may herald postoperative distension and paralytic ileus, for there may be accumulation of intestinal fluids rich in chlorides within the distended gut Whether or not chlorides are present in the urine depends on the chloride intake and it must be remembered that a patient having water alone may have a normal convalescence although chlorides are absent from the urine for five to ten days In a patient with ileus, the presence of chlorides in the urine is particularly reassuring to the surgeon It means, of course, that treatment has restored the plasma chlorides to their normal level In difficult cases it is of value to have a daily determination of the blood urea If it rises above 60 mg per 100 c cm, the fluid intake should be increased and the plasma chlorides and alkali reserve determined

The intelligent administration of fluids after operation adds much to the comfort of the patient, and may favourably influence the prognosis The underlying principles are simple, and if followed, even in difficult cases there is seldom need for elaborate biochemical control of the blood

The following routine has been established

1 *After an operation on the stomach or small intestine or when peritonitis is present*—First day nothing by mouth, morphia gr 1/6 or heroin gr 1/12 six hourly, 3000 c cm 1·5 normal saline in tap water per rectum Second day 3000 c cm per rectum Third day: if percussion is audible, fluids by mouth, 600 c cm and 2100 c cm per rectum Fourth day fluids by mouth

2 *After an operation complicated by vomiting* (e g with acute dilatation of the stomach vicious-circle vomiting)—Pass nasal catheter through nose into stomach, and establish continuous drainage with a Wangerstеen apparatus Start intravenous drip, giving 3000 c cm 4 per cent dextrose 0·18 per cent NaCl (one part of normal saline to four parts of 5 per cent dextrose) In addition, give normal saline in equal volume to the fluid withdrawn from the stomach This volume should be retrospective to the time the vomiting began

3 *After an operation such as excision of rectum or colon, when rectal fluids cannot be given, or retained*—Give intravenous fluids for two days If a blood transfusion has not been given, give 600 c cm of normal saline to cover blood lost, followed by 3000 c cm 4 per cent dextrose, 0·18 per cent. NaCl and, 3000 c cm the following day

1 *In a patient with established dehydration*—It has been shown by Coller and Maddock that patients who already show signs of dehydration have lost at least 6 per cent of their body-weight, a patient weighing 10 st has lost 3000 c cm The patient must receive this allowance of normal saline plus the usual daily fluid intake In a patient who is dehydrated from loss of saliva and diminished fluid intake, as in a carcinoma of the oesophagus, it is sufficient to give half normal saline This is true also in cases of pyloric stenosis

Our thanks are due to Prof J Paterson Ross in whose wards this work has been carried out, and to Dr G Graham and Prof R V Christie for their advice in the preparation of the paper

"A modern industrial and democratic society, by reason of its economic complexity, cannot suffer it if it to become anarchical If it is not permitted to develop creatively into a Christian society it must become a totalitarian tyranny"—From "The Price of Leadership" by J Middleton Murry, London, 1939 Quoted in *Nature Lond* Aug 26 p 345

THIRD INTERNATIONAL NEUROLOGICAL CONGRESS

THIS congress was held at Copenhagen from Aug 21 to Aug. 25 under the presidency of Dr. Christiansen. Earlier in the summer there was some question of postponing the congress in view of the uncertain international situation, but it was finally decided to hold the congress as originally arranged. Crises considered, the attendance at the congress was remarkably good, although the contingent from Great Britain was smaller than it would have been in more settled times; it was however led by the president of the previous congress, Dr. Gordon Holmes.

The congress sessions were held in the University of Copenhagen and the opening was performed in the presence of H M. the King of Denmark and Iceland. The morning of the first day was devoted to a discussion on the *endocrine-vegetative system* with reference to neurology. Sir Henry Dale gave an account of the chemical transmission of the nerve impulse in the sympathetic and parasympathetic systems and at the end-plates of motor nerves J F. Fulton discussed the relationship between the endocrine glands and the vegetative nervous system. He mentioned the nervous connexion between the hypothalamus and the pituitary; through the pituitary hormones both thyroid and ovaries are also under the control of the central nervous system He developed the theme of varying levels in the nervous system for the integration of autonomic reflexes, the degree of complexity of the integration increasing at the more rostral levels, both the hypothalamic and cerebral cortex levels had important rôles in the control of the endocrines Laruelle of Brussels showed a series of beautiful histological preparations of the parts of the central nervous system which are anatomically connected with the autonomic system Further papers on related subjects were given by Gagel from Breslau and Forsberg from Oslo The afternoon was given over to short papers which had some connexion with the morning's theme, the most interesting being Macdonald Critchley's on disorders of nocturnal sleep in narcoleptics in which he added to the classical description of the narcolepsy-cataplexy syndrome a number of minor phenomena including feelings of semi-paralysis and hypnogogic hallucinations Symptoms of these types suggested that narcolepsy is a total disorganisation of the physiological mechanism of sleep.

The discussion on the second day was on a subject of less general interest to British neurologists, that of the *heredo-familial diseases*, especially from the genetic aspect The principal papers were by Bernard Sachs (this paper was read by Riley) on the relationship between amaurotic family idiocy and the other disorders of lipoid metabolism such as Niemann-Pick disease, by André Thomas of Paris on the hereditary cerebellar atrophies, by Curtius of Berlin and the Rumanians, Jonesco-Sisesti and Stroesco, on the genetic aspects of the problem; and by Schaffer of Budapest on the general pathology of hereditary nervous disease A film of congenital myotonia in goats was shown by G. L. Brown and A M Harvey from the Medical Research Council's institute at Hampstead and they also showed myograms demonstrating that the myotonic response to percussion persisted after complete denervation of the muscle and after curarisation, this indicated that myotonia was a property of the muscle-fibres themselves. A short paper which was based on a family studied at the National Hospital Queen Square, demonstrating that certain cases diagnosed in infancy as Oppenheim's disease were in reality examples of a congenital myopathy was read by J. W. Aldren Turner

There were no scientific discussions on the Wednesday, as the day was given over to expeditions to Elsinore and other places of interest in North Zeeland. On this day most of the British participants in the congress had to return to England for reasons connected more with psychiatry than neurology, and the account of the last two days of the congress is therefore not at first hand.

On the fourth day the congress divided into six sections concentrating on varying unrelated aspects of neurology In a paper on the *pathology of the cerebral astrocytomas*, Scherer of Antwerp pointed out the frequency with which parts of the tumours showed the structure of glioblastomas, a phenomenon which he did not think bore any relationship to the age of the tumour or to surgical intervention In the therapy section there was a communication by Madelaine Brown and J. H Talbott from Boston on the value of *potassium salts in Menière's syndrome;* they reported that several patients who had received no *benefit from dehydration had benefited considerably* from a high intake of potassium; since this form of treatment had been started at the Massachusetts General Hospital surgical intervention for Menière's syndrome had not been required.

In the section devoted to epilepsy, Lennox read a paper on the *electro-encephalographic records of relatives of epileptics* In a group of 110 parents or siblings of epileptics he found abnormal records in 51 per cent, this was nine times the incidence of abnormality in a normal control group. In 34 families both parents were examined and in 91 per cent at least one of the parents showed a definitely abnormal record. He concluded that electro-encephalography was a practical aid in the control of epilepsy by means of eugenics. A further paper by Lennox, on the *use of diphenyl hydantoin in epilepsy*, was based on the work of Merritt and Putnam from Boston, they concluded that it was of considerable value in cases of grand mal and psychomotor seizures which were not relieved by phenobarbitone, and, surprisingly enough, found that few patients were intolerant and no serious complications had occurred.

In the neurological surgery section papers were given by Mixter on *rupture of the lower lumbar intervertebral discs*, by Oljenick on *occipitation of the atlas and its clinical syndrome* and by Olivecrona on the *treatment of acoustic neuromas*

The last day was given over to a symposium on neurological results of the *avitaminoses* especially in the peripheral nervous system. The rôle of vitamin-B_1-lack in the ætiology of polyneuritis, and of nicotinic acid in the production of pellagra were the subjects most discussed. Wechsler from New York gave a comprehensive account of the relationship between B_1-deficiency and peripheral neuritis; he objected to the word neuritis on the ground that there was no evidence of inflammation: instead he wished to introduce the term polyneuropathy for polyneuritis in which vitamin-lack or any other non-infective agent seemed to be responsible He placed a large and mixed collection of types of polyneuritis in the deficiency class; thus he thought that neuritis associated with arsenic, diabetes and even phosphorus might have avitaminosis as an additional and possibly ultimately determining factor. He suggested that not only B_1 but the rest of the B complex, and even vitamins A, C, and D might be of importance for the nutrition of the central and peripheral nervous system Ungley's paper described a number of cases

of polyneuritis, some of them associated with gastro intestinal lesions, which appeared to be due to deficiency of vitamin B, while Teglbjaerg from Denmark discussed the treatment of nervous disease with vitamins, he pointed out that chronic nervous changes may result from avitaminosis, but are irreversible in spite of treatment with large doses of the essential vitamins

Sir Edward Mellanby's communication dealt especially with the effects of lack of vitamin A on the nervous system, many of the degenerative lesions found both in the spinal cord and peripheral nerves in experimental animals, which were previously thought to be due specifically to lack of the vitamin, were in fact due to overgrowth of bone causing pressure on the nerves and cord It had not been decided yet whether this bony overgrowth was the only factor causing the changes in the nervous system Unfortunately an important paper from the Oxford school by H M Sinclair could not be given This worker has tried to get objective evidence of vitamin B_1 lack in neurological conditions by estimating the amounts present in the blood both of total vitamin B_1 and of its phosphorylated form or cocarboxylase Such work is a valuable addition to clinical studies on the subject

As well as the scientific discussions, there were the usual social accompaniments of a medical congress, including an evening reception given by the city of Copenhagen in the town hall

THE BASTARDY (BLOOD TESTS) BILL

REPORT OF THE SELECT COMMITTEE OF THE HOUSE OF LORDS

LAST December Lord Merthyr introduced in the House of Lords a bill to enable courts of summary jurisdiction to order blood group tests to be made in bastardy cases The bill provided that when either party demanded a blood test the court should be obliged to order it, and that if the woman refused her application should be dismissed The test should be done by a registered medical practitioner approved by the Lord Chancellor To save expense his report should be admitted as evidence of the facts contained in it, but he could be called as a witness by the court or either party Whether the man was excluded by the result of the test from suspicion of paternity or not, the report should be before the court, but if it was inconclusive no comment on it should be allowed In the discretion of the court, costs should be payable out of the funds which are at the disposal of local authorities for the defence of poor prisoners The Lord Chancellor would be given power to make rules governing the whole of the legal and serological procedure, and he would be assisted in this task by an expert advisory body consisting of legal and medical members

The bill was given a second reading in February and was referred to a select committee of the Lords This is often done when a bill contains new and controversial proposals The committee is usually eight or ten strong and has power to summon witnesses, it is assisted by the legal advisers of the Government The present committee was presided over by Lord Strathcona and Mount Royal and included in its personnel Viscount Dawson of Penn and the Bishop of Salisbury The committee held several sittings during the summer and examined magistrates barristers solicitors pathologists and others Its report was published on Aug 18

NEED FOR THE TESTS

The committee declared that it was unanimously of opinion that the qualities of blood underlying blood grouping, and the laws of inheritance governing the transmission of these qualities from parents to children, are accepted by such a consensus of scientific opinion throughout the civilised world as to render it desirable in the interests of justice for this knowledge to be applicable to affiliation cases It made certain amendments in the bill as originally drafted, and recommended that the amended bill should be passed into law Although the tests can only exclude paternity in about one case in three where the man is innocent, the committee agreed with the Home Office that nevertheless the tests might prevent an injustice being done in these cases, and any method which reduces the number of cases in which the courts may make mistakes must be welcomed The committee was satisfied that the risk of error in the making of blood tests has been reduced to negligible proportions, and that the tests not only might but would prevent injustice It noted that the public are becoming ready to accept the positive verdict of science when it declares that a man cannot be the father of a particular child

The committee was much impressed by the fact that the preponderance of medical and legal opinion was emphatically in favour of the use of blood-tests as evidence in affiliation cases, also that the testimony of two out of three critics of the bill, though of value and interest as regards bastardy law in general, was not directed against the validity of blood tests as evidence and was largely irrelevant to the purpose of the bill Mr Dunne, a stipendiary magistrate, who was strongly in sympathy with the main object of the bill, urged that these are civil cases and that to make it mandatory on the court to order a blood test would be an interference with "the liberty of the subject", and that a mother would have some justification for objecting to the taking of blood either from herself or from her child The committee felt that although these cases are technically civil, yet they require special treatment in view of the social repercussions and possible injury to reputation they involve It did not think that too much weight should be attached to the suggested interference with "the liberty of the subject" if the tests can be carried out under conditions which would admit of no doubt as to the validity of the results An attempt was made by two non medical witnesses representing the National Council for the Unmarried Mother and Her Child, to prove that science is not yet sufficiently advanced to justify the use of blood tests in court The committee was more impressed by the unanimously favourable testimony of the eminent pathologists who gave evidence, and saw no alternative to accepting the conclusion that blood tests carried out by approved experts would render reliable and valuable assistance to the courts in affiliation cases

LEGAL PROBLEMS OF THE BILL

The committee concluded that when a blood test is demanded by the man, the court should be obliged to order it and that in other cases it should have discretion to do so It had also to consider whether there should be any exceptions to the rule that the refusal of the woman should bring about the dismissal of her application As the responsibility of taking the blood samples would invariably rest with a qualified medical practitioner, they concluded that no cognisance need be taken of the very exceptional

cases, such as the presence of hæmophilia, in which the taking of blood might be detrimental to health.

If the bill became law it would not be of much use unless it made some provision for paying the expenses out of public funds, for most of the parties are poor. Certain witnesses pointed out that to impose such costs upon the local funds would not only be a burden on the rates, to which the county councils strongly object, but would also introduce an extension of legal practice The balance of the evidence was, however, in favour of the charge being imposed on the local funds, and with this view the committee was in complete agreement. It dealt at some length in the report with the probable cost of blood-tests, and did not think it likely that the cost to a local authority in any one year could amount to more than £170—an insignificant amount in view of the large funds handled by these bodies. There would also, it remarked, be some saving to public funds in a reduction of the number of poor defendants sent to prison for default It might justly have suggested that the existence in law of the bill would probably cause a considerable reduction in the number of bastardy applications.

The committee therefore decided that blood-tests, within their own domain, should be sufficient evidence of the facts shown thereby, unless the pathologist should have attended the court at the instance of the court or of a party, in which case he would be liable to cross-examination The court should have discretion to demand security for costs, and to order the payment by either party or out of the local funds of the costs not only of the test but also of the attendance in court of the pathologist. These provisions were in the bill as drafted.

DETAILS OF PROCEDURE

A very difficult practical problem with which the committee was confronted was the question of the rules to be made by the Lord Chancellor governing the procedure and the composition of the advisory body The committee considered different suggestions for the composition of this body, made by Mr. D. H Kitchin, Dr G Roche Lynch and Dr. S C. Dyke It concluded that Mr. Kitchin's was the best and, subject to the agreement of the Lord Chancellor, recommended that it be adopted This plan provides for a board consisting of ten members, five legal and five medical, the legal members to be nominated by the Lord Chancellor and the professional bodies, and the medical members by the three Royal Colleges, the Medical Research Council and the British Medical Association A set of suggested draft rules was submitted to the committee and is appended to its proceedings: these contain a detailed scheme for the approval of pathologists and testing centres and for the taking, testing and identification of samples

The committee recommended that there should be two approved testing centres with the prospect of increasing them to four if required Provision should be made for blood samples to be taken by a registered medical practitioner, who should if possible be the woman's regular medical attendant. It recommended that the court should not have power to order a new test, but that on appeal the court of quarter sessions, though not a divisional court or other appellate court, should have power both to take into account the test produced to the lower court and to order a second test if it thinks fit This power for quarter sessions to order a test is a valuable addition to the bill as drafted, but its denial to the divisional court is rather puzzling; judges of the King's Bench Division would be hardly likely to misuse it. The question was raised whether in any circumstances the approved person should be compelled to submit his test to another pathologist for confirmation. It was pointed out that this compulsion might give rise to doubts as to the validity of tests in general. The committee was satisfied that a single test is sufficient and that it is unnecessary to impose confirmation as a duty.

The committee accepted the opinion of the majority of the pathologists that the blood samples should be forwarded untreated and not diluted with a preservative It was satisfied that a standardised system of identification by means of coloured test-tubes would make the risk of error negligible, and that samples sent by post in strong wooden containers would arrive in good condition. Finally, it recommended that the child and its mother should always be required to appear together to undergo the test.

HEALTH IN FACTORIES

FACTORY work is, thanks to sane industrial legislation, becoming steadily more safe. Dr J C. Bridge, senior medical inspector of the Home Office, has a similar story to tell with regard to the health of the factory worker in his section of the annual report of the Chief Inspector of Factories[1] for 1938. Parts of the Factories Act, 1937, deal with general health, and employers have been very willing to conform with them.

The eye-protection provisions have been greatly extended but the cry still goes up that workers refuse to wear goggles. In one large ophthalmic hospital in London the education of workers is attempted by an exhibition of eye-protection appliances, it seems unfortunate that the lesson should be learned only after an eye injury has occurred.

The number of cases of *lead poisoning* has fallen from 141 in 1937 to 96 in 1938; whereas in 1900 the number was well over 1000, it is now for the first time under 100, in spite of the fact that since 1927 building-painters have been included in the figures It was sometimes found that lead paint was being applied by means of a spray, but after the danger was pointed out the brush method was substituted. Leadless paints also are being used more and more. Two cases of *mercurial poisoning* were reported, one in a thermometer-maker and the other in an electric-metermaker.

Of the nine cases of *aniline poisoning* four were unusually severe (aniline oil caused two of them, paranitrochlorbenzol vapour the third and para-toluidine for the fourth). The remaining five cases were slight and were brought about by contact with trinitrotoluol in a shell-filling factory No cases of chronic *benzene poisoning* were reported during the year, but investigation of a boy with leucopenia engaged as a cellulose sprayer showed that he had been using for 14 weeks two cellulose solutions, one of which contained toluene and the other 30 per cent. of benzene

Toxic jaundice is a portmanteau term; of the four cases notified during the year three occurred in a chemical works and were due to arseniuretted hydrogen and the fourth was caused by trinitrotoluene in a shell-filling factory One of these cases of arsine poisoning presented a difficult problem, apart from a slight lemon-yellow tinge of the skin of the face, there was no evidence of jaundice, and death occurred within two days of exposure, as compared with the usual average of five days. Dr. Bridge remarks that

1. Cmd. 6081. H M Stationery Office Pp. 133 1939 2s.

he had not previously seen arseniuretted hydrogen poisoning without definite jaundice, but the post-mortem examination, which was not performed until five days after death, revealed no sign of decomposition, the cheeks and nose were bright pink in colour and arsenic was detected chemically in the various organs Three other fatal cases of jaundice were investigated and in these there had been exposure to fumes from chlorinated naphthalene wax, a substance which is known to cause a skin affection called "wax rash" or "chlor acne" Two of the fatal cases had this condition as well as jaundice The third, a girl aged 21, had been employed at a radio works for nine months, three feet away from where the wax was being melted in small shallow electrically heated trays Slight malaise for two weeks preceded the onset of jaundice After treatment at home for a fortnight she was removed to hospital where she died two days after admission Of 6 other women who worked in the same department, 2 were found to have suffered from jaundice, and 3 others complained of nausea, dizziness and drowsiness Blood-tests to exclude Weil's disease were in each case negative The precautionary measures to suppress the fume consisted in regulating the temperature of the wax pots, covering them, and applying exhaust ventilation

An increase in *anthrax* occurred during 1938, there being 34 cases with 5 deaths as compared with 23 with 4 deaths in 1937 Dr Bridge comments that a satisfactory method of disinfection of hides and skins is yet to be found The dust from wool (shoddy) is used as a soil fertilizer, and one case of anthrax occurred in a factory where shoddy was handled, in another factory where two cases occurred, the only possible source was found to be bone meal obtained by grinding in India of sun dried and unsterilised bone Another case occurred in a builder's labourer, employed in mixing mortar with hair from goat skins fellmongered in this country and therefore not coming under the Order in Council as regards disinfection In the five fatal cases treatment was delayed by failure to obtain medical attention or in correct diagnosis, and Dr Bridge emphasises the value of supplying workers in dangerous processes with the small official anthrax card (Form 1803) This card is shown by the worker to his doctor, who is thus reminded to think of anthrax and delay in treatment is thereby prevented

An increase in *chrome ulceration* (115 in 1938, 14 more than in 1937) took place thanks to the use of anodic oxidation in aircraft production *Occupational cancer* still continues Pitch and tar were the carcinogenic agents in 103 cases with 8 deaths, and paraffin or shale oil in 62 cases with 13 deaths Of the pitch and tar cases, 23 came from patent fuel works, 57 from tar distilling plants, 11 from gasworks and 12 from other industries, the majority (58) of the mineral oil cases occurred in cotton mule spinning and only 4 in other industries At a nickel works 4 more cases of cancer have occurred, 2 of the nose and 2 of the lung

Most of the reported cases of *gassing* were due to carbon monoxide Men working with blast furnaces tend apparently to take unnecessary risks, in 10 cases, of which 5 were fatal, gassing took place during attempted rescue of others

There were 430 deaths from *silicosis* and 9 from *asbestosis* in 1938 Efforts are being made to find efficient substitutes Examples include the use of alumina for flint in china bedding and for siliceous material in the parting powders used in foundries, of non siliceous abrasives for sand or flint in blasting, and of non-siliceous material for kieselguhr (used in the slow cooling of steel) and for silica bricks (for lining steel or other furnaces)

The list of causative agents of dermatitis appears to be unlimited and new items have to be added each year Two cases in 1938 were due to ultramarine In each case the length of exposure was four years A series of 25 cases of dermatitis on the hands and arms of girls employed in canning carrots was investigated There is little doubt that the carrot juice was the primary causative factor Experiments showed that a positive patch test could be obtained with certain extracts of carrot The spread of infection by roller towels is generally held to be a remote risk but Dr Bridge describes an outbreak in a factory of an infective skin condition which was thought to be spread by the use of communal towels The firm was advised to suspend from work all persons suffering from the acute infection, to substitute individual paper towels for the roller towels, and to have the wash basins regularly disinfected These precautions were put into operation and no further case has occurred in the factory

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

BLOOD TRANSFUSION SERVICE

THE appeal for 25,000 donors for this service is meeting with a slow but steady response The service is open to all healthy men and women between the ages of 18 and 60 and people who are already engaged in other emergency services are permitted to enrol as donors Early last week over 200 of the required 1500 had volunteered in Aberdeen and in Edinburgh over 300 out of 5000 In Glasgow the figures were slightly better Blood banks have been started in the main centres of population The main organisation centres are Edinburgh J R Copland, 22 Gilmore Place, Glasgow, Town Clerk's Office, City Chambers, Dundee, Royal Infirmary, Aberdeen, Public Health Offices, 4 Albyn Place In addition to these centres, prospective donors may apply to any local hospital, and the profession in Scotland is asked to encourage members of the public to volunteer

NEW PROFESSOR IN ABERDEEN

His numerous friends in Edinburgh and elsewhere are delighted at the appointment of Mr W C Wilson, F R C S I, to the regius chair of surgery in the University of Aberdeen This appointment is, of course, consequent upon the resignation of Prof J R Learmonth, who is succeeding Sir David Wilkie in Edinburgh Mr Wilson is well known for his work as a children's surgeon and for his research work on burns and on many physiological problems, notably in relation to the nervous system and the humoral transmission of nerve impulses He is a prominent member of the group of surgeons who believe that research in pure and applied physiology constitutes the most useful field for the advancement of surgical and general medical knowledge As a worker in and lately as director of, the surgical research laboratory in Edinburgh University and as director of the surgical research unit in the Edinburgh Royal Infirmary, he has brought honour to the Edinburgh medical school Edinburgh's loss will be Aberdeen's gain This is the third exchange which has taken place between these two Scottish schools within a year

PUBLIC HEALTH

EPIDEMICS IN RECEPTION AREAS

THERE are two distinct epidemiological dangers in reception areas. First, the evacuated children may introduce disease among the less immune natives: secondly, the rural conditions may expose the evacuated children themselves to infections from which they are not immune The dangers to the native children are primarily diphtheria, scarlet fever and streptococcal throats, measles, whooping-cough and other fevers which may not have been prevalent in their area for some time Further in rural districts there is the danger of water-borne infection by carriers among the evacuated children. The evacuated children themselves may be assumed to possess more immunity to the usual children's fevers than the natives For them the main risks are water-borne and milk-borne diseases to which they are not immune

The main water-borne risks are fevers of the enteric group and the bacillary dysenteries Both these may also be spread by milk, as may be scarlet fever, diphtheria, undulant fever and tuberculosis. In urban areas much of the milk is pasteurised, in rural areas very little Therefore immunity from milk-borne diseases must be assumed to be rare among the evacuated children Certain general precautions may be recommended. Where water is not piped, it should be boiled before being drunk All unpasteurised milk should be boiled. Where sewage is not piped, it should be disposed of well away from, and if possible on a lower level than, wells. Children unused to the earth-closet should be warned to take simple precautions against contaminating the soil Those in charge of evacuated children have their hands well filled and the imposition of these additional labours will not be welcomed But should typhoid, dysentery or any other milk- or water-borne epidemic break out, the difficulties of treatment will be considerable Isolation hospitals in rural areas are usually small and not easy to get at Ambulances will be wanted for other purposes and home nursing will be more trying than in normal times

In the past two years THE LANCET has published a series of articles on the control of the common fevers It is felt worth while to summarise the main points made by this group of expert contributors

ENTERIC FEVER

Season September–November. *Incubation period* 14 (7–21) days *Second attacks* rare. Enteric is spread mainly by milk and water and occasionally by insect vectors It is prevented by the proper disposal of sewage, the detection of carriers, the boiling of water and the pasteurising or boiling of milk

Active immunisation—T A B. vaccine given at intervals of 7–10 days (two to three doses) gives considerable protection, which is maximal soon after the last dose. Ideally it should be given in the absence of an epidemic In the face of an epidemic inoculation does improve the chances if the subject is not already infected, but if infection is already present, the typhoid is likely to be worse—the so-called "provocative" typhoid In a rural area vaccination of contacts will do more good than harm in spite of the risk of provocative typhoid. In an urban area with a temporary and remediable breakdown of water-supply, vaccination of the potentially infected is not advised, since the chances of provocative typhoid are considerable and the immunisation gained is not in time to help Antityphoid serum may be given to contacts in two doses at 14-day intervals, thus ensuring some protection for six weeks or more. The practical value of this is, however, small (Topley 1938)

SCARLET FEVER AND STREPTOCOCCAL INFECTIONS

For scarlet fever, *season* September–November. *Incubation period*. 3 (2–4) days *Isolation period* 6 weeks (4 weeks if mild) *Quarantine period* for contacts: 10 days *Second attacks* rare The chief methods of spread of scarlet fever and other streptococcal infections are by direct contact between individuals (including nurses and doctors) who are not necessarily ill Occasionally milk is infected from a human carrier and streptococci have been found on toys and fomites. In institutions, contacts may be Dick-tested and temporary passive immunity established with 5–10 c cm of antitoxin Outside institutions, the clinical and bacteriological detection of carriers is seldom practicable, unless they are prematurely discharged patients, with running ears or other foci of infection. Children sleeping in dormitories should have their beds placed alternately feet to head, so as to increase the distance between the sources of droplet spray. The liability of the streptococcus to produce either scarlet fever or sore-throat must be remembered (Allison 1938)

BACILLARY DYSENTERY

Season. Summer and autumn. *Incubation period*. 4 (1–7) days As a mild gastro-enteritis, bacillary dysentery is much more common in England than is generally recognised It can often be diagnosed only by very early bacteriological examination of the stools, and it has to be distinguished from food poisoning due to salmonella organisms and toxins Large epidemics are rare When they do occur they are usually due to massive infection of water or milk Sporadic outbreaks in family groups are more usual. The condition is often endemic in children's wards and mental hospitals Chronic carriers are probably only important in institutions. In the outside world spread is almost always from case to case, though often some of the cases may be so mild as to escape medical attention The contamination of food, cooking utensils, milk and water may occur from the hands of sufferers

The types commonly met with in England are those due to the Flexner organism (causing dysentery of moderate severity), and those due to the Sonne group (mostly mild cases) Shiga outbreaks are always imported from abroad and are therefore rare. They are the most severe, and serum is only worth using therapeutically in such outbreaks

Apart from general measures of control for water and milk, the most important steps to check an epidemic are isolation of the patient whenever practicable and nursing under strict conditions, the stools being treated as are enteric stools Such isolation may be stopped after one week of well-formed stools In deciding when to stop isolation, it is useless to rely on bacteriological tests of stools, as negative tests are of no significance.

No standard method of vaccine prophylaxis has yet been worked out, though vaccines have been used with considerable success. A suitable vaccine contains 150 million each of the five common Shiga types of organism, and the same number of Sonne strains per ml The Sonne strains must have been recently isolated and not subcultured too frequently The dose for such a vaccine is 0·5–1 ml according to age, and is best given subcutaneously. In institutions inoculation should be carried out once a year (W. M. Scott 1938).

DIPHTHERIA

Season: September–November (worse in dry years). *Incubation period*. 3 (1–4) days. *Isolation period*.

SEROLOGICAL CONTROL OF MEASLES

Nature of serum	Dose in c.cm	Dosage factor	For prophylaxis		For treatment
			Protection	Attenuation	
Convalescent	5–20	Age × 2	1st–5th day after exposure	5th–9th day	Within 6 days of onset of disease
Normal adult	10–40	Age × 1	1st–3rd day	3rd–9th day	Dosage factor age × 4
Whole blood	Double serum	Age × 4			Route intravenous
Placental extract	7·5–30	Age × 3			

4 weeks *Quarantine period* 12 days *Second attacks* may occur Hospitalisation of most, if not all, cases of diphtheria has been the practice in this country for many years This however does not diminish the incidence of the disease Spread is from patients and carriers, who may be convalescent or healthy, and the organisms may pass by droplet spray or by milk to the patient The most dangerous source of infection is not the occult carrier but the child with an overt blood stained yellowish nasal discharge It is possible and indeed probable that a number of such children are among those evacuated

Immunisation has been going on slowly in many urban districts, but is rare in rural districts In 1937 Chester headed the list with 45 per cent of its child population immunised Birmingham, Walsall Worcester, Leeds, Manchester and Chatham were in the 35–40 per cent. group The London boroughs vary greatly Acton in 1937 led with 30 per cent, but the average was only 5·3 per cent

The *prophylactic* method of choice is probably the alum precipitated toxoid (A P T) One may give 0·2 c.cm followed four weeks later by 0·4 c.cm of A P T The minimal interval between the two doses is two weeks. One injection alone is of little value The results should always be checked if possible by the Schick test Passive immunisation by the injection of 1000–2000 units of antitoxin will protect exposed children for three weeks It is best to precede this by a Schick test It may be followed immediately by active immunisation but A P T or formol toxoid (F T) should be used as these contain no horse serum Diagnosis must not wait upon a bacteriological report The tellurite test has a high percentage of error and should therefore not be used Treatment should begin the moment a clinical diagnosis is made Active immunisation has been said to increase the number of carriers (by preventing some of these from developing the disease) and thus to increase the risk of infection in the unprotected The evidence on which this statement is based is doubtful and the immunisation of nurses in fever hospitals has not increased their carrier-rate (E. H. R. Harries 1939)

WHOOPING-COUGH

Season Spring and autumn *Incubation period* 14 (7–21) days *Isolation period* 4 weeks if quite fit at the end of that time—even if still whooping (some authorities still recommend 6 weeks) *Quarantine period* 3 weeks *Second attacks* never occur Whooping cough shows a biennial periodicity alternating with measles This year in England whooping-cough is likely to be severe In its treatment vaccines are useless and convalescent serum of little value It is most dangerous in children under two years of age, and in a family where one case occurs it is worth while to give any other children under two years 10–20 c.cm of parental blood intramuscularly thus producing a temporary immunity Prophylactic immunisation with a vaccine is not yet really in the sphere of practical politics It will definitely attenuate attacks (a valuable hygienic measure in as much as permanent immunity is then ensured) but it will not prevent attacks (Cruickshank 1938)

CEREBROSPINAL FEVER

Season Winter and spring *Incubation period* 4 days In this condition carriers are probably extremely common but susceptibles rare Epidemics are only likely to occur in crowded quarters such as barracks The best prophylactic measure so far known, apart from the proper ventilation of sleeping quarters, is for all in contact with a case to gargle with 1 1000 potassium permanganate Treatment is now a question of chemotherapy

POLIOMYELITIS

Season August–September *Isolation period* 6 weeks. *Quarantine period* 3 weeks Epidemiologically poliomyelitis is somewhat similar to cerebrospinal fever, that is to say, carriers are common but susceptibles are rare Child contacts are more dangerous than adult carriers Isolation of patients and contacts is the only effective control measure. Where the school is the only meeting place for children, as in very scattered rural areas, closing the school is said to be of value The case for closing residential schools is still debated If the children are dispersed, they must go into quarantine Treatment with convalescent serum is of small value only, and vaccines for active immunisation are useless (MacNalty 1938)

MEASLES

Season December–January, and May–June *Incubation period* 14 days *Isolation period* 10 (9–14) days *Quarantine period* 16 days Measles in England shows a biennial periodicity and 1939 is not a measles year Treatment with immune convalescent serum in doses of 10–50 c.cm has been used, but its value is not proved In prophylaxis isolation alone is useless Immune serum will give complete protection for 14–21 days It is specially indicated for children under three years of age and in patients exposed to infection and already suffering from some other disease in whom measles might prove very dangerous In general attenuation with normal adult serum is the ideal to be aimed at The intramuscular dosage with the different varieties of serum and blood, and the results, are shown in the table above (Gunn 1938)

UNDULANT FEVER

Incubation period 14 days. Not less than half the herds in this country are infected with the *Brucella abortus* The condition is twice as common in males as in females and is uncommon in children Infection is always from cattle either by direct handling or via milk or milk products Pasteurisation or boiling definitely makes milk safe, tuberculin tested milk is not safe (Dalrymple Champneys 1938)

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month; his name can be seen later in the half-yearly index

FROM D.P.M.

II

AMONG the compensations of middle age is the fun of watching one's contemporaries turn into their parents I can remember thinking, when I was a child, that my friend's parents were acts of God. I could not imagine them younger or older; they were portents as ageless as the pyramids and rather less explicable That they had begun differently and grown to that pattern never once occurred to me; I must have been a dumb child. Nowadays I can watch them being created before my eyes; and though I find it pleasant, it alarms me because I know I am undergoing the same process To be so constantly aware of the change is disconcerting: it makes one feel unreal and ephemeral on the one hand, and permanent and indestructible on the other. It lends point to the remark of the geneticist that a hen is simply the device of an egg for producing another egg, but robs it of any sting; for obviously the device has a more amusing time than the egg

One sign of maturity which I detect in my friends and myself is a taste for gardening. As far as my experience goes, gardening is not particularly popular with the young—possibly because the gardens in which they are invited to spend their energy are seldom their own Anyhow, I can recall being irritated by the sight of my parents pottering round the garden, and I remember turning sulky when I was asked to help; and now I am among the potterers and getting grimier in the nail-beds as the years go by The other day a young man told me in an angry voice that his parents thought of nothing but their garden, and I looked at him commiseratingly The mark of the potterer is on his brow; in another fifteen years, Hitler permitting, he will be out among the bean-rows, I expect.

* * *

How is it that experts in occupation therapy have made no particular use of dramatic performances as treatment? To prepare and perform a play is a highly social activity, everyone is involved on more or less equal terms, and with a little organisation everyone can be given as much to do as he will stomach. Scenery, lighting, costumes and stage-management can be trusted to keep any number busy, the musical programme will usually provide a full-time job for anyone with a trace of talent; and the acting itself is a gift to the psychotherapist Young things who fancy the world against them can release much of their self-pity in a sympathetic part; those who never attract notice can be sure of the attention and applause of a roomful of people; and the unattractive clumsy one, guided by a skilful producer, can win the affection of the whole house as a comedian. Add to this the pleasant touch of excitement which clings about the theatre and you have the perfect atmosphere for restoring and maintaining mental health In fact after one or two productions probably the only person in need of psychotherapy will be the producer; but in the combined cause of art and science who would not sacrifice a producer or two?

Gas masks for children between the ages of two and five, I am told, are decorated with pictures of Mickey Mouse What a civilisation! German infants, presumably, would see through such hollow entertainment; judging by Clare Leiser's "Nazi Nuggets," quoted in last week's *New Statesman*, Mickey has lost his public in Germany: "Mickey Mouse is the most miserable ideal ever revealed . . Healthy emotions tell every independent young man and every honourable youth that the dirty and filth-covered vermin, the greatest bacteria carrier in the animal kingdom, cannot be the ideal type of animal" However, I can't help feeling that there are German babies who disappoint their preceptors in this, and continue to find the gallant and resourceful Mickey as attractive as the brave little tailor of their own fairy tales.

Until recently I had the impression that most people in this country were kindly disposed towards the German people, as distinct from their leaders and political system, but a night or two ago, happening to remark that it was agreeable not to have to feel rancour towards the Germans themselves this time, I was depressed to find that hardly anyone agreed with me The room was full of young people who no doubt were justified in resenting bitterly the overthrow of their future; but it was saddening all the same to hear the ghostly phrases of 1914 echoing through their conversation—"no peace until they are stamped out"—"break Germany up"—"all the young people in Germany are longing for war"—"root and branch." The Prime Minister has told us, with splendid discrimination, the evils we are fighting: brute force, bad faith, injustice, oppression and persecution He is right, those are the things we want to destroy—if we can find a way to hit the target Unfortunately, as in all wars, we shall be fighting many who hate these things as much as we do, the few who uphold them will be shielded by armies of just and honest men If we can keep this in mind we shall do a little better than we did last time Once or twice in the last few days I have found myself thinking of a remark which Sir James Barrie once made to the students of Edinburgh University, a great remark in my opinion. I quote it from memory, and probably inaccurately: "Do not attribute to your enemy motives meaner than your own. Nothing so debases the moral currency Give it up and be great."

* * *

The trouble about this war, or so I think after five hours of it, is that it is too well organised There is none of the haphazard, go-as-you-please atmosphere which I seem to recall in 1914, with the theatres playing to crowded houses and everyone feeling brisk and disorderly. Perhaps this, being a Sunday war, is bound to have some of the atmosphere of the traditional English Sunday; or perhaps I see the last war—"The War," as we used to call it in our innocent way—through a golden haze However, I am not really qualified to give an opinion because I find on thinking it over that nearly all my memories of the last war are gastronomic True, I was a growing child at the time, if that can be regarded as an excuse, but it had not occurred to me before what

a greedy one I must have been The thought of returning to the diet of those days hardly troubles me now, perhaps my soul no longer resides in my pylorus, though I have no evidence of its taking up any other situation It will even be amusing in a way to see the old menu cropping up again That indefatigable codfish, for example, is he still waiting to lay down his life for us, pale, flaccid, slippery, and tasting of wet cotton wool? Shall we see that queer substance honey-butter replace jam? Will sugar mysteriously convert itself to saccharine, and the hens give up laying as a protest against the European situation? Will potatoes turn hard, blackish and semi translucent, like rather grubby candle grease? Worst of all, must we again face rice pudding made with dried milk? That pudding really excites my indignation, even in retrospect I can remember air-raids too, but without acrimony For some reason that rice pudding will stick in my gizzard till I die

OBITUARY

ARTHUR LAUNCELOT FLEMMING

M B BRIST, M R C S, D A

Dr Flemming's death last week at his home at Clifton will be keenly felt in Bristol, where he did so much for the teaching and proper establishment of anæsthetics at the Royal Infirmary The son of a Freshford practitioner, he went to school at Somerset College and Hermitage House, Bath, going on to Bristol University and medical school After taking his M R C S in 1894 he held resident appointments until he was attracted to the war in South Africa, where he became surgeon to the Princess Christian Hospital Returning to Bristol for his degree in 1910 he began to specialise in anæsthetics and was registrar and anæsthetist first at the women's and homœopathic hospitals, later at the orthopædic hospital, and finally at the infirmary He was also well known to London anæsthetists as an assiduous attender of the sectional meetings of the Royal Society of Medicine, he was president of the section of anæsthetics 1922–24 He also played a part in the formation of the Association of Anæsthetists, serving on its first elected council He was a sound rather than a profuse writer on professional topics and had a literary sense which served him well as editorial secretary for many years to the *Bristol Medico Chirurgical Journal* He was president of the Bristol Medico Chirurgical Society 1926–27 All who knew him were impressed with his directness and sincerity

JOHN GRAY

M D EDIN

Dr John Gray reader in pathology at the British Postgraduate Medical School at Hammersmith, died last week in his fortieth year He had been in failing health for two years and the end was not unexpected None the less, his death comes as a loss not alone to pathological teaching and research but to a wide circle of friends Gray came from Edinburgh, where he attended George Heriot's school, serving as a private in the Highland Light Infantry in 1918 He then had a brilliant career in Edinburgh University, taking first place in almost every subject and the Cunningham, Vans Dunlop, Murchison and Stark scholarships After graduating in 1923 he held the Allan fellowship in clinical medicine and surgery, assisted in the anatomy department and did some research on the embryology of the pituitary gland He was then house physician to the Royal Infirmary and in 1925 passed from there to Aberdeen as senior assistant in pathology and later lecturer, holding concurrently the Leckie Mactier fellowship awarded him by Edinburgh In 1927 he took his Edinburgh M D with gold medal for a thesis on nephritis and six years later, at the request of the Medical Research Council, he expanded this thesis into a monograph which was published as Special Report (1933) No 178 The establishment of the radium centre enabled him to study the histological effects of irradiation on malignant growths and diseased tissues, his studies included hypernephroma, endothelioma, rhabdomyoma and peri arteritis nodosa In Aberdeen it was his duty to report to the hospitals on all autopsies, these numbered well over a thousand during his period of office, and he had a good deal of medico legal work to do on behalf of the procurator fiscal It was in 1934 that he left Aberdeen for Hammersmith with the reputation of a lucid and informed lecturer, there he helped to create the liaison between clinician and laboratory staff by organised discussions which were something new and highly satisfying in medical teaching The regard in which he was held was heightened by his modest bearing and the easy way in which he carried his learning

CHARLES HEWITT MILLER

C B E, M D CAMB, F R C P

THOUGH he left the London Hospital in 1925, Dr Miller was very much a London Hospital man Educated first at Rugby and Trinity College, Cambridge, he qualified in 1901, and after holding many house appointments at the London acted as director of the pathological institute there from 1905 to 1907 He did not want to become a pathologist and he joined the staff of the Victoria Hospital for Children in 1906, the Metropolitan Hospital in 1909 and the Brompton Hospital in 1912 But his clinical medicine was founded, more than most men's, on observation in the post-mortem room and he carried into practice the painstaking method of the morbid anatomist Since failure to observe is the usual cause of failure in diagnosis, he was a good diagnostician, and his habit of carefulness was transmitted to his students It seemed to them—as indeed it was—part of the hospital tradition

In 1913 Miller was appointed assistant physician to the London, and when the late war came he saw distinguished service, he ended the war as a full colonel, having been consulting physician to the British Expeditionary Force and twice mentioned in despatches After demobilisation he was created C B E Meanwhile he had been elected F R C P in 1916 and in the following year had delivered Goulstonian lectures on the paratyphoid infections which may be read in our columns On Jan 19, 1920, he took charge of the

newly established medical unit at the London Hospital, and as first director served nearly five years He was an exacting teacher, a stickler for thoroughness in clinical examination, never hurried and intolerant of slackness. But if he was sometimes impatient with his clerks he was never impatient with the sick. A big heavily built man, with a somewhat heavy clean-shaven face and a slow manner, he was gentle in his approach and sensitive in mind.

His writings were not many. He was especially interested in peptic ulcer and its consequences, and in the relationship between the gall-bladder and cardiac pain. In this last indeed he took a very personal interest, for it was an attack of coronary thrombosis, and the ill health that followed, that made him give up his busy consulting practice. In a letter to THE LANCET in August, 1934, signed "Live and Learn," he gave an account of this attack, of how eighteen months later he decided to start practice somewhere else on a more leisurely plan, and of how he gradually regained power to do almost anything he liked, from ski-running to salmon-fishing. This letter, like one or two others it inspired, is full of useful information for anyone with cardiac pain, and it has the charm of sincerity and self-revelation.

The place Dr. Miller chose for his new practice "on a lower level of action" was Exeter, where he was appointed to the staff of the Royal Devon and Exeter Hospital. "It was not long," writes a Devon practitioner, "before he was in great demand as a second opinion. His wide knowledge of medicine, his simplicity and his great good sense came as a breath of fresh air to those of us who called him in to help with our problems It was felt that, if anybody could clarify a situation, he could; and his therapeutic suggestions were always practicable and never complicated. His lectures to the Devon and Exeter Medico-Chirurgical Society and his remarks during discussions on cases were conspicuous for sanity and he never used a long word where a short one would serve the purpose"

The last phase of Miller's career began with his appointment in 1937 to the staff of University College Hospital, where approaching retirements were likely to leave the physicians a group of unusually young men. Here it was his primary task to fill a gap, but he did much more.

Dr. Miller died on Aug 29 at his country home, Littlewick Place, near Maidenhead. He was the son of Charles James Miller of Manchester and was born at Eccles, Lancashire, in 1875 He married in 1908 Phyllis Tarbutt, and she survives him with two daughters

R. H. writes: "In Charles Miller we have lost a physician of the characteristically British type, for he was an excellent clinical observer, guided always by sound practical common sense, rather distrustful of the newer 'scientific' medicine and an admirable bedside teacher. His complete sincerity was apparent to all who came in contact with him, for he had a hatred of all that was false or pretentious and his bluff hearty manner endeared him to his friends, whilst the outspokenness with which he expressed his opinion made him respected by his opponents. He was, indeed, a 'white' man through and through His later years were clouded by ill health which he bore with stoicism, but the high compliment which was paid to him by his election as senior physician to University College Hospital was a source of great pleasure and encouragement. He died very suddenly, fortunate in that he did not live to see the actual outbreak of the present war to which, from his experience in the last, he had looked forward with horror. His home life was singularly happy, and deep sympathy will be felt for his widow and his two daughters"

LETTERS TO THE EDITOR

NEUROSIS OR PSYCHOSIS?

SIR,—Dr. Gillespie's comment on your leading article of Aug 19 is perhaps based upon misunderstanding of the view taken by at least some who hold that the difference between neurosis and psychosis is quantitative rather than qualitative. He supposes that this view implies that "since the neuroses are but mild psychoses, and since psychotherapy is of little use in the latter, so it is of minor importance in the former" These assumptions require scrutiny. It is true that certain aspects of the mental disorder encountered in the psychotic—such as relative inaccessibility and lack of insight—obstruct or prevent the use of psychotherapy. Nevertheless there are psychotic patients who undoubtedly do benefit from this form of treatment Apart from the question of scientific accuracy therefore, I believe one of the disadvantages of a qualitative distinction between neuroses and psychoses to be this, that it may encourage the physician, having labelled a patient psychotic, to assume that psychotherapy cannot help him.

Dr Gillespie's second assumption, that if the quantitative distinction be accepted and it be admitted that psychotherapy is of little value for the psychoses, therefore it is of minor importance for the neuroses, is surely unfounded. Because operation is of little use in certain advanced cases of malignant disease it does not follow that it is of minor importance in the treatment of more circumscribed growths of the same histological type

I am entirely in agreement with Dr. Gillespie in his objection to the recognition of lay psychotherapists In fact I believe that if a man is to become a good psychotherapist he must needs first be a good doctor

Finally, Dr. Gillespie quotes from my lecture words which, when detached from their context, appear to contain an overstatement. I accept of course Dr. Gillespie's view that there is room, and more room, for specialist psychotherapy, and that the man who has had a long training and devotes himself entirely to this work, can achieve results—especially in the more difficult cases—which are beyond the reach of the ordinary practitioner. But it is the ordinary practitioner who has to, or ought to, treat the great majority of neurotic patients, and for him some simpler and shorter training must suffice Moreover, I believe that the simpler forms of psychotherapy, as opposed to the more recondite, are very often successful

So much has now been written about the different methods of psychological treatment, especially the analytic kind, that the general practitioner is apt to be frightened of the subject altogether, apt to feel that, unless he has had a prolonged course of training, he cannot tackle his neurotic patients with any hope of success This view I believe to be wrong I

maintain that a good doctor, with the right personal qualities and with a few fundamental principles to guide him, can learn from his own experience to be a good "general" psychotherapist That is to say, he will be able to treat most of his neurotic patients successfully The exceptional cases he will refer to the specialist

If, then, adequate provision is to be made for the treatment of the neuroses, those who are responsible for medical education should have two objects in mind One is the training of specialists in the more recondite methods of psychotherapy, the other is the training of the medical student and general practitioner in the shorter and simpler methods

It was to an audience of medical students that my lecture was addressed

I am, Sir, yours faithfully,

Henley-on Thames, Sept 3 C P SYMONDS

PULMONARY TUBERCULOSIS AND ANTUITRIN S

SIR,—From the response of one case of pulmonary tuberculosis to treatment, it is useless to attempt to prove anything But for the war, I should have tried out what I now describe on a series of patients As it is, I leave the proof or disproof of my inferences to others I feel I must, however, record my findings, firstly because they were so dramatic, and secondly because they were, for theoretical reasons, expected Further, the antithesis of the treatment nearly killed a control patient

The theoretical observations which led me to try out my new line of treatment were as follows Pulmonary tuberculosis is a common disease in young women It is especially common in the flat breasted, thin, under developed, sexless type with scanty periods, this type does not do well Although amenorrhœa is produced by any disease which causes cachexia, anæmia and ill health in pulmonary tuberculosis, it is often present before these have appeared After sexual activity or child bearing, the type of female I mentioned often becomes more physically fit and sexually developed (assuming she has not yet had tuberculosis) I therefore suggest that in as much as immunity depends upon physical fitness, it depends also upon a sound set of endocrines With these thoughts in mind I tried out a pituitary preparation as a therapeutic measure to increase the resistance of one of these poorly developed tuberculous women

A female, 34 years of age had been suffering from schizophrenia for 13 years She made no mental improvement during this time but till two years ago her physical health remained satisfactory She then started to lose weight gradually but not consistently, gaining in some months and losing in others Three months ago the fall in weight became continuous at the rate of 1 to 3 lb per month I first saw her on July 9 this year She had abnormal physical signs at her right apex, her sputum contained tubercle bacilli, and the X ray showed advanced right sided unilateral pulmonary tuberculosis She had had amenorrhœa for some years but this was probably secondary to her mental disorder She had only a slight cough and had never had a hæmoptysis She was seen by a consulting physician who suggested that the disease had been present for two years in as much as her weight had fluctuated for that time

She was treated symptomatically and from July 9 till August 12 she ran an intermittent temperature rising every night to about 100° F The pulse varied between 110 and 120 On August 14 she was given 2 c cm of Antuitrin S, and the dose was repeated every other day for four doses in all It was then raised to 5 c cm still on alternate days for another four doses On the day after starting this treatment her pulse dropped to 90 and has never since risen above 110 On the eighth day her temperature was normal and has since never risen above normal

During July she lost 8 lb in weight In the last three weeks she has regained this to within 2 lb

The antithesis was when I tried giving Antuitrin G to a similar patient, there was a considerable rise of temperature and pulse

I know only too well that tuberculosis shows remissions and exacerbations, but in the case I have described I ventured to expect this remission, and it followed immediately upon starting treatment

I am, Sir, yours faithfully,

Orpington, Kent, Sept 3 D G PRICE

A PEACE OF UNDERSTANDING

SIR,—Your leading article under this heading must have been to many like a bright and helpful light, giving a lead for constructive effort when the need for it is great During the twenty-five years since 1914 medical psychologists and psychiatrists have fully confirmed in clinical practice the superiority of sympathetic understanding over coercion as a basis for the control of anti social violence in individuals whose mentality is unbalanced This knowledge is surely the best available basis for an effective long-term policy aiming at the elimination of similar destructive urges in the international field

But, as you pointed out last week, to deal with the disruptive force of this kind of aggression we need a moral courage to face the evils in our own human nature If we are to make of this war—or rather of the peace which we and our allies hope to be able to shape when it is over—something better than a repetition of the mistakes made from 1914 onwards, it is essential that enough of our people, and especially those in authority, should find this moral courage

The lead might well come from those of our profession whose experience enables them to agree at once with the views which you have expressed, since they at least can recognise the harm done by their own mistakes The difficulty is to put forward these views in such a way as to enable others to accept them It would be a fatal error to embark on propaganda which might appear to those to whom it is addressed as an accusation of moral turpitude, conscious or unconscious We all know that the inevitable result of such an approach is to strengthen the defences against conviction My hope is that the lead which you have given may bring together a few hundred medical men and women who will first discipline themselves so that they may eliminate all appearance of self righteousness and superiority from their relationship with the public They might even set themselves the task of achieving unanimity in their pronouncements and publish an account of their difficulties in this achievement, in sufficient detail to show that they have had to overcome the same weaknesses in themselves which they invite others to tackle

I venture to suggest that you should make available for distribution to the public copies of your leading article of last week, or an adaptation of it addressed especially to them, and, so that no individual need assert himself as the prime mover, you should take the initial steps in bringing together those who wish to act vigorously in the direction you have indicated

I am, Sir, yours faithfully,

Devonshire Place W 1 Sept 5 J NORMAN GLAISTER

LANDING AT DOVER

SIR,—In Grains and Scruples of your issue for Christmas week, 1937, I made an appeal for funds to allow some care to be taken at Dover marine station of the Austrian and German domestics then entering the country in large numbers and often in a state of collapse after their journey. The sum of £45 15*s* was collected and, as this fund is now to be wound up, those readers who generously subscribed to it may like to know how the money was spent and what it is proposed to do with the balance remaining. It may be mentioned that the two largest donations came from the German embassy and an anonymous donor.

The London branch of the Travellers Aid Society, who administered the fund, found a German-speaking resident of Dover who proved to be the ideal person for the task. For a small weekly sum, she met every day during the twelve months from January, 1938, the two boats on which most of the foreign domestics arrived. The nature of the work done can best be shown by some extracts from this lady's reports:—

February.—During this week I met approximately 250 foreign maids who passed through the port of Dover. These consisted of Austrians, Hungarians, Swiss and Germans. All could speak German but not one had a working knowledge of English I met them before they passed through the passport office and explained what they would have to do in regard to passport, medical and customs examinations and from which platform their train would go. I helped as much as I could with the translation at the medical office and customs.

. . . I have also been able to help with outgoing maids, as yesterday when an official asked for my help with an Austrian maid who had lost the only boat for Ostend She was very frightened and had very little money but I was able to find her a cheap lodging in the youth hostel here and then see her off by the boat next day.

March.—All of these girls are in real need of help . . they are almost overcome with fatigue and seasickness They are in most cases of a simple nature, coming as they do from little villages and farms, and they are quite at a loss to know what to do on arrival: I often am asked to fill in their landing cards.

Many of them have but the vaguest of ideas where their destinations are . . Girls weeping bitterly who have lost or mislaid their suitcases, others who are desperately anxious because they have missed their train and a regrettable few who are not allowed to land and stand bewildered and downcast wondering how they will return to their own country. . . it is touching to see their gratitude after some soothing explanations in their own language.

It is pleasant to record the helpfulness of the officials; the recognition of the work by the Southern Railway, shown by their reservation of two compartments for the girls; the kindness of the station caterers, Messrs Frederick Hotels Ltd, in allowing tea to be obtained at half-price; and the generosity of the large majority of porters who forwent their usual tips in needy cases Finally, a generous tribute has been paid in the annual report of the medical inspector of aliens at Dover—who first pointed out the need for the work—that it had "earned the gratitude of some 9000 weary, homesick, hungry servant girls who arrived at Dover during the year"

At the end of January, 1938, the Travellers Aid Society (London branch) became amalgamated with the National Vigilance Association and about the same time the society's worker found herself obliged to give up the work. Fortunately by this time a radical change had occurred, chiefly as a result of the discouragement by the German authorities of their nationals from taking up domestic service abroad Some Germans and Austrians continue to enter with permits for domestic service but they are nearly all refugees of a somewhat different social class. Swiss, Hungarians and other nationalities still enter but they seem to be better organised and cared for It is the general opinion that the work may now be *given up without much hardship and it is* proposed to hand over the balance of the money subscribed, £17 3*s*, to another fund with similar objects · the Germany emergency committee of the Society of Friends would seem to be an appropriate recipient.

I am, Sir, yours faithfully,

Aug 10 CIVIL SERVANT

*** It may still be of interest to put on record a piece of beneficent work now so completely closed—ED. L.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUG. 26, 1939

Notifications.—The following cases of infectious disease were notified during the week: Smallpox, 0; scarlet fever, 1170; diphtheria, 745; enteric fever, 62 (57 "expected"), pneumonia (primary or influenzal), 328; puerperal pyrexia, 183; cerebro-spinal fever, 19; poliomyelitis, 34; polio-encephalitis, 2; encephalitis lethargica, 2; dysentery, 32; ophthalmia neonatorum, 85. No case of cholera, plague, or typhus fever was notified during the week

Deaths.—In 126 great towns, including London, there was no death from smallpox, 1 (0) from enteric fever, 2 (0) from measles, 1 (0) from scarlet fever, 14 (5) from whooping-cough, 16 (2) from diphtheria, 32 (5) from diarrhœa and enteritis under two years, and 15 (2) from influenza. The figures in parentheses are those for London itself.

Chesterfield reported the only death from typhoid Fatal cases of diphtheria were scattered over 12 great towns, Sunderland and Birmingham each reporting 2. Sunderland had 5 deaths from diphtheria, Birmingham 3

The number of stillbirths notified during the week was 240 (corresponding to a rate of 36 per 1000 total births), including 35 in London

The Lancet 100 Years Ago

September 7, 1839, p 867

From a report of the proceedings of the British Association.

We must notice an important practical suggestion of Professor GRAHAM at greater length, as it may be the means of saving many lives He observed that the *afterdamp*, or carbonic acid, left in the atmosphere of a mine, after explosion, is supposed to occasion in many instances a greater loss of life than the explosion, at the same time it renders assistance impracticable. In many cases the oxygen of the air is not exhausted by the explosion, although, from the presence of five or ten per cent of carbonic acid, it is rendered irrespirable The atmosphere will be rendered respirable by withdrawing carbonic acid, and he suggested a method by which this might be effected. He found that a *mixture of slaked lime and pounded Glauber's salts, in equal proportions*, has a singular avidity for carbonic acid, and that air might be purified completely from that deleterious gas, *by inhaling it through a cushion of not more than an inch in thickness, filled with that mixture*, which could be done without difficulty

---

". . . Alfred Marshall avoids the term 'standard of living' and distinguishes between the *standard of life*, meaning 'the standard of activities adjusted to wants,' and the *standard of comfort*, 'a term that may suggest a mere increase of artificial wants, among which perhaps the grosser wants may predominate.' 'A rise in the standard of life implies an increase in intelligence and energy and self-respect; leading to more care and judgment in expenditure, and to an avoidance of food and drink that gratify the appetite but afford no strength, and of ways of living that are unwholesome physically and morally.'"—STUART A. RICE, *Science*, Aug. 25, 1939, p 167.

PARLIAMENTARY INTELLIGENCE

FROM THE PRESS GALLERY

Military Service from 18 to 40

IN the House of Commons on Sept 2, Mr ERNEST BROWN, Minister of Labour, asked leave to introduce a bill to render all fit male British subjects of the ages of 18 to 40 inclusive liable to be called up for service in the armed forces of the Crown during the war emergency He said the bill itself did not in general directly place a liability on these citizens to be called up for service, but it provided for a proclamation to be issued from time to time Men liable to be called up for service would be required to register, they would be medically examined and they would receive their enlistment notice The procedure for these purposes would be similar to that which had been applied in respect of militiamen under the Military Training Act

Sir DENNICK GUNSTON said that undergraduates at the universities under the Military Training Act were allowed, and indeed compelled, to postpone their service He wished to know whether this new measure would abolish such postponement of service

Mr HORE BELISHA, Secretary of State for War, said for all intents and purposes the Military Training Act fell to the ground, and was replaced by this bill The young men who had obtained postponement under the Military Training Act would fall within their age groups, and would be entitled to seek postponement in the way provided in the present bill

Leave was granted, and the bill was read a second time On Sept 3 the bill passed through all its remaining stages in both houses and was given the royal assent

Compensation for War Injuries

On Sept 2 in the House of Commons Sir WALTER WOMERSLEY, Minister of Pensions, asked leave to introduce a bill to make provision as respects certain personal injuries sustained during the period of the present emergency He explained that the object of the measure was to provide for grants in respect of personal injuries or death caused by air raids, or other operations of war, to the civil population The injury allowances were designed to be immediate emergency payments to tide a man over the first results of an injury Treatment would also be given immediately under Ministry of Health arrangements at local hospitals, or by private practitioners, if the case was not sufficiently serious to go to hospital After sufficient time had elapsed to judge the conditions, if it was found that the case involved serious and prolonged disablement, then the bill provided that a pension might be granted for a period or permanently, as might be required by the circumstances Pensions would be awarded on service lines, that was to say, in accordance with the medically certified degree of physical disablement The bill suspended the exercise of rights under the Workmen's Compensation Acts, or rights at Common Law, or under contract, in the case of incapacity for work caused by war injuries or war service injuries The grant of injury allowances and pensions would take the place of any compensation which a man might otherwise be able to obtain by an action at law

Dr HADEN GUEST asked whether the class of case in which primary injury might be trivial, but the final injury might be very serious, would be adequately looked after There were many cases, he said, where an injury to the head appeared at first to be nothing much more serious than a scalp wound followed in a little time by a headache, but finally there might be found an actual effusion of blood below the skull, causing pressure on the brain and giving rise to very serious nervous conditions or even sudden death Unless a preliminary injury was very carefully diagnosed and recorded those cases might be very difficult to deal with, because there would not be adequate evidence of how the injury occurred Another class of injuries which was likely to occur under war conditions were psychic injuries, apart from the purely physical nervous apparatus, as a result of which, after a considerable period, a person might suffer from a nervous condition directly attributable to the injury, although the injury might have been at the beginning a very small thing Omission to pay adequate compensation to an individual injured might be safeguarded against if provision was made that all war injuries, especially those likely to lead to nervous or psychic disturbances, were very carefully recorded at the time they took place

Sir WALTER WOMERSLEY said he had secured a committee of eminent medical specialists on nervous diseases, who would make to him a full report He would then be able to act on their report, as upon other matters that might be brought forward from time to time by expert medical advisers

Leave was granted, and the bill was read a second time On Sept 3 the bill passed through all its remaining stages in both houses, and was given the royal assent

War Service and Health Insurance

On Sept 2 in the House of Commons Mr ELLIOT, Minister of Health, asked leave to introduce a bill the main object of which, he said, was to secure that persons insured under the scheme of National Health Insurance contributory pensions did not suffer any loss of rights under those schemes by reason of joining the armed forces of the Crown, or entering upon war occupations The bill provided, in effect, that on return to civil life all such persons would find themselves in the same position as if they had been continuously in insurable employment throughout their period of service or war occupation There was a further provision in the bill dealing with the adjustment of health insurance benefits and contributory pensions to payments which were made in respect of war injuries or pensions paid in respect of death due to war In effect the bill merely secured that double payments from public funds were not made in respect of the same event, the approved societies, that was to say, were safeguarded against having to make payments for which no financial provision was made in the scheme of national health insurance There were further provisions to the effect that insured persons would be able to secure payment of benefits or pension although the records affecting their title might not be available when the claim arose, due to the possible destruction of records as a result of the war

Leave was granted, and the bill was read a second time On Sept. 3 the bill passed through all its remaining stages in both houses and received the royal assent

---

Surgeon Commander J F M CAMPBELL, M B, has been appointed to the Admiralty and will serve as assistant to the Medical Director General in succession to Surgeon Commander A W North L M S S A, who, after four years there, has received another appointment

Dr W HARVEY SMITH died on Sept 1 at Merriden, Warwickshire, where he was equally well known as family doctor, county magistrate, sportsman and raconteur For 35 years he was medical officer to the local poor law institution Always a lover of animals he was as much at home with their injuries and diseases as with those of his human patients When he reluctantly gave up his dogcart it was for an open car in which he always drove in one gear He was in his 84th year

Dr P W MACLEAN, who died on Aug 30 at the age of 68, had practised in Bradford since 1912 when he retired from the Navy as staff surgeon His wife is Miss Phyllis Hambledon the novelist

MEDICAL NEWS

Society of Apothecaries of London

At recent examinations the following were successful:

Surgery.—J. V. Braithwaite, W. D. Jenkins, E. A. Milner, T. Owen, D. B. Roberts, E. Smith, H. F. Sparling, E. Wolfendale and H. Woolwich.

Medicine.—E. J. S. Barthorpe, A. N. Boyle, R. M. Coplans, M. E. Davies, D. H. Dracup, R. H. Gaman, T. L. B. Iredale, J. Lieber, M. C. Mair, E. C. G. Miller, E. A. Milner, D. Prysor-Jones and G. L. L. Reynolds.

Forensic Medicine.—E. J. S. Barthorpe, A. N. Boyle, R. M. Coplans, M. E. Davies, D. H. Dracup, R. H. Gaman, T. L. B. Iredale, J. Lieber, M. C. Mair, E. C. G. Miller, E. A. Milner, D. Prysor-Jones and G. L. L. Reynolds.

Midwifery.—C. Bucknall, D. W. Burnford, P. S. Clarke, G. O. C. Davies-Webb, W. Gordon, K. P. D. Griffiths, S. T. Nakib, K. W. N. Palmer, V. N. Stevenage and M. Venugopalacharli.

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery and midwifery:

A. N. Boyle, Manc.; R. M. Coplans, Middlesex; D. H. Dracup, Lond. Hosp.; K. P. D. Griffiths, Charing Cross; T. L. B. Iredale, Leeds and West Lond.; J. Lieber, St. George's, E. C. G. Miller, Melb.; D. Prysor-Jones, L'pool; E. Smith, Oxfd. and Guy's; V. N. Stevenage, Madras and West Lond.; and H. Woolwich, L'pool.

University of Aberdeen

As reported by our Scottish correspondent on p. 617, Mr. W. C. Wilson, director of the unit for clinical research in surgery at the Edinburgh Royal Infirmary, has been appointed regius professor of surgery in the University.

Joint Tuberculosis Council

This council has arranged to hold a course in radiology at the clinic, Shire Hall, Castle Hill, Cambridge, from Sept. 20 to 22. A course in the diagnosis and treatment of pulmonary tuberculosis in Lancashire will be held at the Tuberculosis Offices, 352 Oxford Road, Manchester, from Oct. 10 to 14. Further information about these courses may be had from the hon. secretary of the council, Dr. J. B. McDougall, Preston Hall, near Maidstone, Kent.

Research Scholarship in Ophthalmology

A George Brewster and Jennie Mathews honorarium of $1000 is offered through the International Association for the Prevention of Blindness for original work in simple non-inflammatory glaucoma. Papers may be written in English, French, German or Italian; in order to facilitate the task of the jury, papers written in the last two languages should be accompanied by a translation in English or French. Further information may be had from the secretary of the association, 66 Boulevard Saint-Michel, Paris.

Hand-lamps for A.R.P.

The British Standards Institution has drawn up a specification for electric hand-lamps, fitted with a primary battery or unspillable accumulator, for general use during a black-out, either out-of-doors or in buildings in which the windows, roof lights and so on are not screened. The ordinary torch type of hand-lamp is not entirely suitable because no means are provided for preventing the light being directed upwards. The specification provides that the light emitted shall be properly directed and screened. Copies of the specification can be obtained from the institution at 28, Victoria Street, Westminster, S.W.1, price 3d.

The School-leaving Age

The Education Act, 1936, came into force on the 1st of this month. This raises the age for compulsory attendance at school from 14 to 15, and no child born after Sept. 1, 1925, will in future be allowed to leave school before the age of 15 unless he or she obtains an employment certificate from the local education authority.

Badge of Office

The Ministry of Health announces that full-time medical officers of the Emergency Medical Service will wear on their right arm a twill brassard bearing the letters "E.M.S." in deep red on a blue background.

International Congress for Life-saving and First-aid

The fifth international congress for life-saving and first-aid to the injured was held in Switzerland from July 23 to 28. Colonel Patry, vice-president of the international committee of the Red Cross, stressed the need for standardising first-aid equipment for use in major international catastrophes. Among the subjects discussed were first-aid work at sea and in town and in country, and in factories and in mines. Artificial respiration, the treatment of wounds and shock, and the training of the first-aid worker were also considered.

British Association

On Friday, Sept. 1, the remainder of the sessions of the association's meeting at Dundee were cancelled. Sir Richard Gregory, F.R.S., was elected president for the coming year.

Austrian Refugees

The Home Office has received from the Committee of Austrians in England a detailed list of the Austrians who have registered at the Austrian Centre, with an assurance that they will do all they can to help this country in wartime. The list includes 71 chemists, 108 female and 6 male nurses, and 41 doctors.

Local Medical and Panel Committee for London

The functions of this Committee, under the N.H.I. Acts and regulations, are now vested in a controller and an emergency committee of three. The chairman of the old committee automatically becomes the controller, while the committee of three are the former vice-chairman, the former treasurer and the former chairman of the finance and general purposes committee.

EMERGENCY NOTICES

The house and library of the Royal Society of Medicine will be closed for 14 days from the date of the outbreak of war. At the end of that time they will, if possible, reopen.

The staff and records of the Joint Council of the Order of St. John and the British Red Cross Society have been removed to Eastbourne, but the full staff of the ambulance department will remain at the headquarters, 12, Grosvenor Crescent, London, S.W.1.

The offices of the Chartered Society of Massage and Medical Gymnastics have been moved to Mount Lodge, Chesham Road, Amersham, Bucks. The society's annual congress, which was to have been held in London from September 18 to 22, has been cancelled.

The Clinical Research Association has moved to Hilton's Annexe, South Road, Haywards Heath, Sussex. Tel. Haywards Heath 576. Labels with the new address will be forwarded on application.

The *Chemist and Druggist* will for the present be printed at Bath, and all correspondence to the editor should be sent to him there *c/o* The Pitman Press. The inquiry department will remain open at the London office, 26, Essex Street, W.C.2.

Until further notice the address of the Incorporated Society of Chiropodists will be Red Porch, Ashley Close, Walton-on-Thames, Surrey.

The offices of the Medical Research Council, which are at present largely occupied with emergency work, have been temporarily removed to the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1 (Museum 3041).

The offices of the Medical Women's Federation have been moved to 73, Bourne Way, Hayes, Bromley, Kent (Tel. Hurstway 1901).

Births, Marriages and Deaths

BIRTHS

BELL SMITH—On Aug 27, at Waltham Abbey, Essex, the wife of Dr Donald Bell-Smith—a daughter
DAVISON—On Aug 31, the wife of Dr George Davison, of Cramlington—a daughter
GRIFFIN—On Sept 2, at Uppingham, the wife of Dr E M Griffin—a son
JOYCE—On Aug 31 at Hong Kong, the wife of Surgeon Commander A de B Joyce, R.N.—a daughter
ROBSON—On Sept 5, at Llandudno, the wife of Dr J R. Robson—a son
SCOTT—On Aug 29, at Newcastle on Tyne, the wife of Capt. R W Scott R.A.M.C.—a daughter
TULLOH—On Aug 29, at Bournemouth, the wife of Dr E P Tulloh—a daughter
WALLFT—On Aug 27, at Chard, the wife of Dr J F Loader Walley—a daughter

MARRIAGES

ANDERSON—SHARP.—On Aug 27, at Hendon, Anthony Francis Anderson, M B, to Helen Margaret Sharp
CHILD—BOYD—On Sept 3 at Brighton John Peto Child, B M, to Margot Janet Laurie, only child of Sir Hubert Bond, K B E, F R C P
CRIMMIN—POOK.—On Aug 26, at Soho Square Capt George William Crimmin R.A.M.C. to Megan Pook
CROSS—CORBY.—On Sept 2 at Liss, Alexander Galbraith Cross, F R C S to Eileen Longman
DANIELL—BENSUSAN BUTT—On Aug 30 at Colchester, Peter Wilberforce Daniell, to Mary Barbara Bensusan Butt, M B, daughter of Dr Ruth Bensusan Butt of Colchester
MCILWRAITH—LEWIS.—On Aug 26 at Holy Cross, Edinburgh Patrick William Fitzjames McIlwraith L.R.C.P.E, of Edinburgh to Margaret Lewis of Hove Sussex
PHILIP—FLEW.—On Sept 4 at Ealing, William Marshall Philip M B, to Yolande Flew
PORTER—WYATT.—On Sept 1 at Woodbridge, Hugh Lachlan Porter M B, to Barbara Mary Wyatt
SHORT.—PEARCE.—On Aug 26 at Holy Trinity Church Kingsway, Thomas Leonard Hall Shore, M B, to Madeleine Elsie Pearce
SUTCLIFFE—SHELDRAKE.—On Sept. 2, at the Brompton Oratory, Lieutenant William Greenwood Sutcliffe, R A M C, son of Lieut-Colonel D G Sutcliffe, O B E, F R C S, of Margate to Mary Charlotte Sheldrake, of Kelvedon Essex
SHUTTLWORTH RENDALL—HORNSBY.—On Sept 3, at Barnet David Charles Shuttleworth Rendall, M R C S, to Dorothy Hornsby
TELLING—GORDON.—On Sept 2 at Marylebone, Otto Maxwell Telling B M, to Dorothy Gordon
WOOD—JOHNSTON.—On Aug 26 at Enfield, William Wallace Wood M B, to Theodora Johnston M R.C.S

DEATHS

BLACKSTONE.—On Sept 3 at West Worthing, Sussex, Willoughby Arthur Blackstone, M R C S
MARLING.—On Sept. 3 Dorothy Barbara Marling M B Lond
MITCHELL.—On Sept 1, at Old Hill, Staffs, Thomas Ellis Mitchell M B Camb
MILLER.—On Tuesday Aug 29 at Littlewick Place near Maidenhead Charles Hewitt Miller C B E, M D Camb, F R C P, of Portland Place W, aged 64
MILLER.—On Aug 31, Richard Miller, M R.C.S, D T M & H, of Hove
ORR—On Aug 28, at Bangor Ulster William Young Orr, M B Edin D P H late of Putney, S W
RUSSELL RYAN—On Aug 28, John Russell Ryan M D Dubl, aged 77
ROBERTS—On Sept 2 Charles Michael Roberts, M B Lond of Woking, aged 59
THOMSON—On Aug 30 at Firetat France, Major Douglas Thomson M B Dubl D P H R.A.M.C (retd) late Sudan Political Service

CIBA LIMITED state that they have ample supplies of Percaine in its various forms ready for use and, in addition stocks of raw material from which percaine will shortly be manufactured in their new laboratories at Horsham

"It might be imagined that signs of hyperneurousness when facing medical examiners augur ill for an ability to withstand nervous strain This is very far from being the case and many examples can be given of excellent pilots who have been of a hyperneurous type In one instance a pilot, whose war record could only be described as first class, inevitably fainted when sitting in the dentist's chair Many of the pilots who won Victoria Crosses in the war were of a quiet sensitive type, and some were distinctly hyperneurous If a candidate despite a fast pulse a high pulse pressure, and other signs of nervousness can yet show a quiet demeanour and an ability to think quickly, and answer readily, when he faces his medical examiner, it speaks well for his chances of making good"—Group-Captain A P Rook, *J R nav med Serv* July, 1939, p 204

NOTES, COMMENTS AND ABSTRACTS

IMMUNISATION AGAINST SCARLET FEVER IN FINLAND

THE Finnish army is unusually prone to streptococcal infections, manifest as sore-throat and scarlet fever. T. W. Wartiovaara is inclined to attribute this susceptibility to climatic conditions and to the sparse distribution of the community, which prevents young men from meeting streptococci till they are herded together in barracks (*Nord. Med.* June 3, 1939, p. 1671). Be this as it may, there have lately been 500–1000 cases of scarlet fever and 8–17 scarlatinal deaths every year in the army. Dick-testing on a large scale has shown only some 12–14 5 per cent. to be Dick-positive, but the scarlatinal morbidity among Dick-positive soldiers was 20 4 per cent. in 1933 and 14 4 per cent. in 1936, compared with 0 34 and 1 2 among the Dick-negative. Immunisation of the Dick-positive with toxin from an *American strain, Dochez NY5*, has yielded results encouraging as far as comparative freedom from scarlet fever is concerned, but rather discouraging as regards the reactions provoked Sudden malaise, vomiting, giddiness and attacks of shivering have been noted, and although these may be ascribed in some cases to the toxin having been injected into the muscles by misadventure, Wartiovaara records the impression that there is room for improvement in the preparation and dosage of the antigen before inoculation is generally applied.

WHEN THE BOMB FALLS

THE *doctor "on the spot"* brings with him a fund of technical knowledge, a head perhaps cooler than most, and the tools of his trade. Without the last, the others are of little value. The doctor's immediate duty is to restrain the enthusiasm of the first-aid worker. His second is to relieve pain. To do this, he must have a hypodermic syringe, a solution of morphia and a bottle of chloroform. Today doctors should cling as tightly to these as to their gas-masks. Morphia and a syringe can find a place in the pocket, and even chloroform may be carried in a hip flask In the big accident on the District railway at Charing Cross last September, H. J. B. Atkins,[1] who happened to be present, came away with the conclusion that morphia and chloroform were indispensable to the doctor on such occasions Chloroform is rapid in its effects and relatively non-inflammable, and so is to be preferred to any other anæsthetic.

CATERING IN WAR-TIME

THE recipes and menus prepared by the staff of the Gloucestershire Training College of Domestic Science for the use of teachers learning to take classes in war-time dietaries have been collected into a little book (Communal Dietaries in War-time. University of London Press. 1939 Pp 18. 1*s*.). The prescriptions have been tried out on and subjectively approved by the consumers in the college hall of residence, though young nettles, tender dock leaves, bracken and hop shoots, dandelion and sorrel may not be everyone's meat. Useful tables are included which help those who are faced with the problem of calculating tins of peaches, condensed milk and sardines in terms of protein and calories Many of the recipes are unusual and interesting, including one for "faggots," and many sound unexpectedly appetising. They are intended for groups of people larger than the ordinary family, but will appeal to all who wish to base their housekeeping on sound modern dietetic principles.

LIGHTER SIDE OF THE CIVIL SERVICE

WITHOUT the usual background of public-school and university education Mr. R. W. Harris, obviously an inspired examinee, entered the Civil Service as a boy-clerk in 1890. He was first promoted to the India Office and later to "Taxes" where he served with such distinction that he was transferred to Somerset House as assistant to Lord Chalmers This, however, did not mark the summit of his career, for in 1911 he was associated in the pioneer work of national health insurance administration with the great, but little known, W. J. Braithwaite. On retirement Harris became administrative secretary to the London School of Hygiene and Tropical Medicine, and at first sight these later activities might seem to be the only ones likely to interest medical readers In fact this is far from being the case. His book (Not so Humdrum. London: John Lane 1939 Pp. 271. 8*s*. 6*d*) teems with good stories adroitly told, and the author has found fun where others, less observant, might have missed it. At least one reader, having chuckled his way through it, closed the book with regret and a heightened respect for the Civil Service.

A NEW USE FOR OLD X-RAY FILMS

Mr. CLAUDE WHITE, M P.S, writes:—Many of us are wondering how to protect windows from the blast of high-explosive bombs. The following scheme has many advantages. The cost is very small; it takes little time to carry out and, when completed, does not disfigure the windows; and it makes a tidy and attractive piece of work which can be undertaken at odd moments and then forgotten. The basic element in the scheme is the discarded X-ray film. This is stripped of the emulsion and the clean piece of celluloid is attached to the glass window by means of celluloid varnish. The celluloid sheet is thick and robust and will not buckle and kink like the thinner variety one often sees recommended for this purpose Furthermore, it is non-inflammable. Some films have a blue base and these can be reserved for those windows where a slight light loss is of no importance

The best way to clean the plates is to soak them in very hot water, after which the emulsion can easily be rubbed off. *Pin them up to dry and store* till needed under a weight to keep them flat A suitable cement is made up of 5 parts of celluloid dissolved in 15 parts of acetone, to which is added 20 parts of copal varnish. Most hospitals will be glad to part with their discarded X-ray film for the asking. I am aware of quite a number of dispensaries where this method of window protection has been very successfully carried out.

SUBTROPICAL GARDENS

Dr. Jex-Blake has brought out a new edition, not this time of Gray's Anatomy but of "Gardening in *East Africa*,"[1] in which his exactitude and sense of proportion have served him well. It is indeed a practical handbook, for in its 26 chapters it deals in succession with climate, soil, growth factors, manuring, garden planning, horticulture, propagation, and the various kinds of plants to be cultured or propagated, and ends with chapters on garden pests, large and small. Curiously enough, only one chapter is devoted to the home flora, although its value is enhanced by the 10 coloured *plates of indigenous trees, shrubs* and plants which are a feature of this edition It seems that the European in East Africa likes to be reminded of the plants with which he was once familiar, in the same way as the exile in the Swiss Alps tries to grow hollyhocks and strawberries in a landscape of gentians and alpenrose. As an offset to the vast amount of ordered information in the book is a riotous essay on "gardens at the coast" in which Mr. H. B. Sharpe makes the very *shingle to blossom* So wide is its scope that the book may be of value to gardeners in almost any part of the globe.

POSTOPERATIVE THROMBOSIS AND EMBOLISM

MORTALITY AND MORBIDITY

By Robin Pilcher, M S Lond , F R C S

PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON, DIRECTOR OF THE SURGICAL UNIT UNIVERSITY COLLEGE HOSPITAL LONDON

Since 1929 a careful search has been made in this hospital by surgeons and registrars for cases of post operative thrombosis and embolism It is not claimed that no cases have been missed, but records have been kept with care since the decision was taken to make special note of these conditions The diagnosis and recording has been made by many individuals, and the records vary in detail The interest of all members of the staff has been a safeguard in diagnosis, doubtful cases often being submitted to consultation For this reason, the diagnosis if recorded by a member of the staff has been accepted for purposes of this paper even when the evidence for it has not been recorded in detail

The records for the decade 1929–38 have been analysed to show the inter relation of thrombosis and embolism, and the mortality of the latter , the results are published in the hope that they may serve as a basis for comparison with series in which newer methods of treatment such as papaverin or heparin are used Good accounts of these and other remedies are being published, but there is little information available as to the natural morbidity or mortality In the series here presented prophylaxis of one sort or another has been tried, but no specific treatment of the established condition except embolectomy in one case

CRITERIA OF DIAGNOSIS

Since it is not practicable to give case records it is necessary to state the criterion of diagnosis and the extent to which they are fulfilled In both thrombosis and embolism there is a rise of temperature , in a previously afebrile case this is usually noticed, and is, in fact, very often the first indication of anything amiss In a febrile case a slight rise may be unnoticed, and when it occurs cannot be attributed necessarily to any complication It is unusual to find no fever In an afebrile case the onset of fever is probably the best indication of the time of onset of thrombosis It is always a little difficult to date this accurately, and it is usual to find that the rise of temperature precedes symptoms, but sometimes it follows them In simple thrombosis the rise is seldom of more than 1 5° F , but when embolism occurs the temperature rises higher and 101° is not uncommon A single attack of embolism gives a characteristic rise in the temperature chart lasting about 5 days The rise of temperature in a case of embolism often precedes the symptoms, and may be presumed to be due to undetected thrombosis

Thrombosis has only been diagnosed in the veins of the leg I have several times suspected hypogastric thrombosis on the symptoms described by Ducuing (1929), but have not made the diagnosis with certainty For example, there have been two fatal cases in which unexplained retention of urine occurred a few days before death The signs on which thrombosis is diagnosed are delayed cooling on exposure, pain and tenderness, œdema, slight cyanosis and fullness of superficial veins Of these, the most constant are tenderness and delayed cooling , these in conjunction with a rise of temperature would be regarded as evidence of thrombosis Sometimes the diagnosis is made first on the cooling test A patient has an unexpected rise of temperature and the legs are exposed for ten minutes, even if they look normal A marked difference of temperature is suggestive of thrombosis, the thrombosed leg being warmer, and I do not remember any case showing this sign alone which did not subsequently develop others This test is vitiated by operations or inflammatory lesions on the limb in question The degree of swelling is very variable and depends on other factors than thrombosis The impression is widespread that cases with much œdema, the true phlegmasia alba dolens, are less subject to embolism than those with little The signs of thrombosis enumerated above were not all present in every case As an example, out of 141 cases of thrombosis there were 20 in which there was no rise of temperature at the time of diagnosis of thrombosis, although in some it occurred before or after Of these 20 apparently afebrile cases of thrombosis, 9 had pulmonary embolism, some before the detection of the thrombosis In the diagnosis of embolism little importance is attached to the presence of recognised thrombosis and, in fact, in the majority of cases no thrombosis was found Unless, therefore, gross errors are made in the diagnosis of embolism, it must be accepted that many cases of thrombosis are not diagnosed The fact that thrombosis may be latent makes it difficult to assess its risks on the evidence of diagnosed cases

Pulmonary embolism in addition to fever has three important features pain, hæmoptysis, and signs of pleurisy or consolidation The pain is usually pleural, and although sudden in onset does not herald the lodgment of the embolus A large embolus produces a terrible sensation at its presumed time of impaction, but patients able to give an account of this after recovery do not describe it as pain but as a feeling of constriction of the chest associated with terror and a sense of impending death I have several times observed hæmoptysis before pain, and this is not surprising if the pain is caused by a pleural reaction Nor need it occasion surprise that pain is sometimes absent, since it would not be expected unless the pleural reaction were peripheral and it may be interlobar

It is unfortunate that the case records are often incomplete in certain particulars, but definite notes of the four features—fever, pain, hæmoptysis and signs of consolidation or pleurisy—are recorded in 68 cases out of a total of 111 non fatal embolisms Fever was present in all but 2 , in most it was clearly associated with the embolism , in a few there was already fever and an additional rise coincided with the embolism Pain was absent in 2 cases, hæmoptysis in 16 Physical signs of consolidation pleurisy or both were found in all but 3 cases All four signs were present in 48 of the 68 cases with full notes It may appear from these figures that diagnosis has been casual but as already stated it has only been accepted when vouched for by competent observers who have during the period taken a special interest in the disease

ANALYSIS

The results of the analysis are given in tables I II, and III

TABLE I—POSTOPERATIVE THROMBOSIS AND PULMONARY EMBOLISM IN SURGICAL WARDS OF UNIVERSITY COLLEGE HOSPITAL (1929–38)

	Cases
Femoral or crural thrombosis only	98
Thrombosis with non-fatal embolism	43
Non-fatal embolism without recognised thrombosis	68
Fatal embolism	44
Thrombosis or embolism diagnosed in life followed by death from other causes	8
Total	261

TABLE II—ASSOCIATION OF THROMBOSIS AND EMBOLISM

	Cases
1. *Thrombosis diagnosed in life*—	151
With non-fatal embolism (sometimes before recognised thrombosis)	43
With fatal embolism, first attack	3
With fatal embolism, later attacks	4
With death from other causes	3
2 *Embolism diagnosed in life*—	123
With recognised thrombosis	48
Subsequent fatal attacks	10
Subsequent death from other causes	2
Fatal first attacks	34
Total embolism fatal and non-fatal	157
3 *Fatal Embolism*—	44
Thrombosis or previous attacks of embolism	13
Unexpected deaths	31

TABLE III—MORTALITY-RATES

	Per cent
Mortality from embolism after diagnosis of thrombosis	4·6
Mortality from embolism in first attack	21·6
Mortality from embolism in survivors of first attack	8·1
Total mortality-rate of embolism	28·0
Mortality from embolism in all cases of thrombosis and embolism	16·8

As has been mentioned above, the majority of embolisms had no recognised thrombosis It will be seen that the mortality when embolism has been diagnosed is a little higher than when thrombosis only has been diagnosed, but the difference is not statistically significant, being less than twice the standard error of the difference In a previous paper (1937) dealing with fatal cases of embolism only I wrote that thrombosis of the veins of the leg or pelvis was found post mortem more often on the right than the left. In this, which is by contrast a clinical study, the reverse is found The figures are given in table IV.

TABLE IV—DISTRIBUTION BY SIDES OF THROMBOSIS (A) IN NON-FATAL CASES, (B) IN FATAL CASES

	A		B	
—	Thrombosis	Embolism	Thrombosis	Embolism and percentage of embolism
Right	42	15	43	16 (37)
Left	75	20	81	25 (31)
Both	20	7	23	8
Not noted	4	1	—	—

In the cases of thrombosis diagnosed in life there is a marked preponderance of left-sided cases, although right-sided cases show a higher incidence of embolism than left This difference is not significant, but taken with the findings in the post-mortem study referred to, suggests that a right-sided thrombosis is more likely to be complicated by embolism than a left

SUMMARY

(1) During the ten years 261 cases of thrombosis and embolism occurred in the surgical wards of the hospital

(2) The mortality-rate of the whole series was 16·8 per cent. The mortality-rate of the first attack of embolism was 21·6 per cent The total mortality-rate of embolism was 28 per cent

(3) Fatal embolism followed 4·6 per cent of diagnosed thromboses and 8·1 per cent. of diagnosed non-fatal embolisms. This difference is not statistically significant.

(4) In the majority of non-fatal embolisms no evidence of thrombosis was found. The majority of fatal embolisms were unexpected

(5) Thrombosis diagnosed in life is commoner on the left side than the right This is the reverse of the findings in a large post-mortem series of fatal embolisms

THE ERYTHROCYTES-PLASMA INTERFACE

AND THE CONSEQUENCES OF ITS DIMINUTION

BY ROBIN FÅHRÆUS, M D

PROFESSOR OF PATHOLOGICAL ANATOMY IN THE UNIVERSITY OF UPPSALA

BLOOD kept in vitro at body temperature for some hours changes distinctly in certain respects It can be either defibrinated or citrated blood but preferably blood with strong rouleaux formation and a high sedimentation-rate, such as horse's or human blood or blood from any of those countless pathological conditions in which it has a decreased suspension stability When such a warmed sample of blood has reached room temperature and the red corpuscles have been suspended again in the blood fluid by shaking, it becomes clear that their sedimentation-rate has been much diminished By the exclusion of other factors or by microscopical examination it is easy to infer that the reduced sedimentation-rate of the erythrocytes depends on a reduction of their rouleaux formation. Another observation, too, can be made by microscopical comparison—namely, that the thin biconcave disks of the normal erythrocytes have grown thicker and their diameter has diminished

The changes described (Fåhræus 1921) are as a rule well developed after warming for a few hours, and after twelve hours even the strongest rouleaux formation is usually destroyed The sedimentation-rate of the red corpuscles is, as a result, very low perhaps only a few millimetres an hour, and they have become completely spherical Let us say that the blood, when kept at body temperature, spontaneously increases its suspension stability.

In one respect it is easy to analyse the way in which this change comes about It consists partly of a primary change of the corpuscles and partly of a primary change of the plasma, which in its turn has a secondary effect on the corpuscles If red corpuscles, even when washed, are warmed separately and thereafter suspended in plasma, their rouleaux formation and sedimentation-rate are very much less than they were before warming, and the corpuscles become more spherical If blood fluid (serum or citrated plasma) alone is warmed it changes in such a way that red corpuscles suspended in it show reduced rouleaux formation and sedimentation-rate and tend to spherocytosis—in other words, exactly the same morphological changes which the red corpuscles

undergo when they are warmed separately The temperature range within which these changes of the blood fluid take place is 82°–118° F (at least with horse's blood), and they are most evident at about 108 5° F

By comparing the rise in suspension stability of whole blood with the effect produced in an artificial sample of blood in which only one chief component has been warmed, it is easy to convince oneself that the changes in the blood represent the sum of the changes in the corpuscles and in the plasma The primary change of the erythrocytes seems to be less important in increasing the stability than the secondary, which originates in changes in the plasma This applies in a high degree when warming takes place at normal body temperature and in a less degree at high fever temperatures These experiments have in more recent years been continued by Bergenhem and Fåhræus (1936) and by Bergenhem (1939) During this time we have concentrated on the process in the blood fluid, from now on called the stabilisation process The same term can be used for the process which takes place in the red corpuscles but is as yet uninvestigated

Stabilisation Process in Blood Fluid

If red corpuscles are suspended in blood fluid which has been kept at body temperature for some hours, they become, as stated above, more or less spherical and show reduced rouleaux formation and sedimentation rate If this artificial blood is now centrifuged and new corpuscles are added to the clear blood fluid, the new corpuscles behave in the same way as they would in natural blood fluid—i e, they maintain their shape, pronounced rouleaux formation, and high sedimentation rate This simple experiment shows that the spherocytosis and the reduced aggregation of the red corpuscles are caused by their adsorbing a substance which is formed during the warming of the blood fluid and may be called the stabilising substance

Many circumstances point to the fact that the stabilisation process in the blood fluid is enzymatic It has already been pointed out that it has a pronounced temperature optimum at 108 5° F If blood fluid is heated—e g, for ten minutes at 125° F—it is inactivated—i e, the formation of the stabilising substance is completely prevented, however long the blood fluid may be kept at body temperature afterwards Further observations pointing in the same direction are that an enzyme poison, such as quinine chloride, prevents the stabilisation process, and that hydrogen ion concentration has a great influence, the process being retarded in acid solution and strongest in a weak alkaline solution

FORMATION OF LYSOLECITHIN

Bergenhem and Fåhræus (1936) have shown that the stabilising substance is probably identical with lysolecithin produced from serum lecithin by a lecithinase In any case the alcoholic extract of the stabilised blood fluid contains in much greater quantities than does the natural blood fluid a substance which contains phosphorus, which is precipitated by ether, and which when dissolved in water has a haemolysing effect Lysolecithin has hitherto been known as the haemolysing substance which appears when the lecithinase of cobra venom is allowed to act on a substratum containing lecithin This suggestion that the stabilising substance is lysolecithin is supported by the fact that the stabilisation process in serum, inactivated by heating can be activated, and in native blood fluid intensified, by the addition of very small quantities of cobra venom The stabilisation process therefore can be said to give blood fluid pre haemolytic properties The changes which the erythrocytes undergo in stabilised plasma—i.e, spherocytosis and reduced aggregation—can be regarded as a preliminary stage to haemolysis The same can certainly be said also of the spherocytosis and reduced aggregation which take place when red corpuscles alone are kept at body temperature

SEPARATION OF ERYTHROCYTES AND PLASMA

Why is the blood in vivo not changed in the same way as in vitro? Why do the red corpuscles in the vascular system keep their rouleaux formation and biconcave shape, characteristics which they lose after some hours at body temperature in vitro? Or, to put the question in another way, what is the factor which produces the stabilisation process in the in-vitro experiments?

By chance I observed that blood more or less completely kept its rouleaux formation and sedimentation-rate, and the shape of the red corpuscles unchanged when during warming it was kept flowing in the receptacle either by gentle shaking or by slow rotation Misled by the fact that shaking of the blood fluid alone could also in certain cases hinder the stabilisation process—for reasons which were later investigated by Bergenhem (1939)—I believed at first that the inhibition by shaking was due solely to the movement of the blood In other words, the fact that the blood was stationary, which Bergenhem and I (1936) termed the blood's "endopause," was considered to cause in some unknown way the physico chemical conditions necessary for the stabilisation process

Later, influenced by Knisely's (1936) studies of the spleen, we discovered that another explanation was the right one The stabilisation process in stationary blood, both as regards blood fluid and corpuscles, is caused by the separation of these components by sedimentation of the red corpuscles Shaking has an inhibiting influence, therefore, because it continually mixes the red corpuscles and the blood fluid This is the only explanation for the slowing of the stabilisation process in a sample of blood which is stationary except for being shaken up some seconds every half hour But Bergenhem (1939) has proved that other conditions which bring the red corpuscles and the blood fluid together and thus make interaction between them possible also prevent the stabilisation process If, for example, during the warming of stationary blood care is taken to obtain a large contact surface between the red corpuscles and the plasma by keeping a small quantity of blood in a big flat receptacle, the raising of the blood's suspension stability can be hindered nearly as effectively as by shaking

These experiments seem to show that the red corpuscles prevent the blood fluid from receiving stabilising properties, and that the blood fluid prevents the corpuscles from being stabilised, or, in other words, blood fluid obstructs or neutralises the effect of the stabilisation process in the red corpuscles and red corpuscles obstruct or neutralise the effect of the stabilisation process in the blood fluid The nature of these reciprocally obstructing mechanisms is not yet known, but it can certainly be assumed that they take place upon the boundary surface between the corpuscles and the blood fluid—in other words, upon the erythrocytes plasma interface

The following provisional theory for the explanation of the red corpuscles power to hinder the stabilisation process in blood fluid has been given by

Bergenhem (1939) From experiments made by Bloor (1916), Knudson (1917) and Bodansky (1931) it can be assumed that the red corpuscles play an important part in the synthesis of phosphatides and therefore in the lipoid metabolism of the blood. Because of this it is possible that the derivatives of lecithin formed by the stabilisation process in the blood fluid—i.e., lysolecithin and an unsaturated fatty acid—are adsorbed on the surface of the red corpuscles and are there resynthesised into lecithin, this then returning to the blood fluid, and so on in a continuous cycle

No explanation, however, has been suggested of the other mechanism, which enables the blood fluid to prevent the stabilisation of the red corpuscles. Speculation cannot come into the question here before this mechanism is partly explained The only relevant observation that I have found is that the warming of red corpuscles increases the amount of free fatty acids (Weigert 1900)

The uncertainty in these matters, however, does not extend to the question, asked above, how it comes about that blood with a low suspension stability can maintain it in the vascular system for long periods The reason why a pneumonia patient for weeks, a pregnant woman for months, and a horse throughout its life have biconcave corpuscles with conspicuous rouleaux formation and high sedimentation-rate must be that the stabilisation process, as regards both corpuscles and blood fluid, is prevented or has its effect neutralised by the circulation of the blood, which creates the condition for interaction between its main components, an interaction which must be located at the erythrocytes-plasma interface The question then arises whether conditions occur somewhere or at some time in the body which raise the suspension stability of the blood in the same way as this happens in stationary blood in vitro. In other words, has the organism some mechanism which brings about a temporary, but sufficiently long separation of the erythrocytes and the plasma, for the chemical changes which cause stabilisation to take place in the corpuscles, or in the blood fluid, or in both ?

The Spleen as a Reservoir of Blood

As is well known, it was Barcroft (1926) who gave new life to the waning interest in the physiology of the spleen by the rediscovery and rapid advancement of our knowledge of the spleen's function as a reservoir of blood. The significance of this function seemed to be that the organism had at its disposal a reserve of blood which could be mobilised during bodily exertion. This view was confirmed by the fact that the concentration of hæmoglobin was greater in the reservoir blood of the spleen than in the circulating blood But many have asked (Lauda 1933) whether the whole complicated anatomical structure of the spleen, which has no analogy in any other organ, has no other physiological task than to increase the quantity of circulating blood by what, in human beings at least, can only be a small percentage

The difficult problem in the anatomy of the spleen has been its vascular system, together with the closely allied question of the blood's histological whereabouts in the spleen reservoir. Hueck's (1928) idea, the leading one not long ago, was that there could be two ways of circulation of the blood One would be a closed circulation, with a direct connexion between the arterial capillaries and the venous sinuses, to which the circulation would be limited when the spleen was not acting as a reservoir. The open circulation, on the other hand, would be something peculiar to the spleen. By this the blood would pass from the arterial capillaries directly into the intercellular spaces of the pulp, where it would be stored while the spleen acted as a reservoir An important point in Hueck's idea of the spleen's circulatory system was the assumption that the same anatomical units, by transforming themselves, could produce both a closed and an open circulation.

The Spleen as a Separator of Blood

Knisely's (1936) conception is very much simpler but nevertheless surprising. He experimented on living spleens of mice, rats, and cats. Microscopical examination of the blood flow shows that all the arteries open into the venous sinuses, which are linked with the smallest branches of the arteries and of the veins in the same way as ordinary capillaries The circulation in this closed system is regulated by contractions of sphincters situated on the arterial and venous sides of the venous sinuses. The cycle for the blood's passage through the spleen can be said to begin by the closing of the sphincter on the venous side of a venous sinus As a result of this the venous sinus begins to fill with blood and to be distended Simultaneously a separation of the blood's main components takes place, because the blood fluid passes through the walls of the venous sinus to the intercellular spaces of the pulp. When the sinus is completely filled with red corpuscles, the sphincter on the arterial side shuts, and the corpuscles now lie freed from the blood fluid for a shorter or longer time, which in certain cases has been observed to last ten hours. Afterwards the sphincter on the venous side opens again, and the sinus empties into the veins its content of red corpuscles, which thus rejoin the circulating blood

The ordinary histological pictures of the spleen with masses of red corpuscles in the intercellular spaces of the pulp are completely misleading, according to Knisely, and are due to the fact that in the dead or dying spleen the walls of the venous sinuses become impaired and allow the red corpuscles to pass through

The essentials of Knisely's conception are (1) that the blood's main components are separated in the spleen because the walls of the venous sinuses form a filter, through which the blood fluid passes, while the erythrocytes do not, and (2) that the erythrocytes lie packed in the venous sinuses and separated from the blood fluid for long periods In other words, conditions seem to be created in the spleen which ought to produce changes similar to those which take place when red corpuscles are warmed separately in vitro.

ALTERATIONS OF RED CORPUSCLES IN THE SPLEEN

Some earlier observations definitely support the suggestion that the suspension stability of the blood increases during its stay in the spleen. Thus, Hammarsten (1883) said that the red corpuscles in the spleen's blood were less flattened than those in the arterial blood, and that they had a smaller diameter—in other words, that they showed a relative spherocytosis. The correctness of this observation has been confirmed by Bergenhem and Fåhræus (1936) by comparing arterial blood and blood from the splenic vein under conditions which made certain that the latter was reservoir blood About the same time Heilmeyer (1936) substantiated by direct measurement that the erythrocytes become more spherical during their passage through the spleen.

Further, Hammarsten (1883) said that the red corpuscles of the blood in the splenic vein showed

reduced rouleaux formation On my advice Berglund (1930) investigated the sedimentation rate of the blood in the spleen of horses and found on the whole a much lower rate than in arterial blood Similar experiments were carried out later in cats by Mellgren (1936), with extra precautions which assured that actual reservoir blood was used, whereas the reaction with blood from the splenic vein was carried out with the same quantity of red corpuscles as in arterial blood The conclusion can definitely be drawn from Mellgren's experiments that not only the sedimentation rate but also the rouleaux formation is less in splenic blood than in arterial blood At present it is not easy to decide whether these changes of the corpuscles in the blood of the splenic vein are direct —i.e., due to the "deplasmatised" corpuscles packed in the venous sinuses being primarily stabilised— or whether they are partly indirect—i.e., due to adsorption of the stabilising substance (lysolecithin) which is formed in cell free plasma in the intercellular spaces of the pulp To what extent plasma free from red corpuscles is stored in the spleen is not clear, but it seems likely that deplasmatised erythrocytes are stored in greater quantities and longer than is the case with cell free blood fluid It is therefore probably also true that the stabilisation of the blood of the splenic vein is principally due to primary changes in the erythrocytes

Hæmolysis due to Separation of Blood in the Spleen

It has long been believed that the spleen plays an important part in the physiological destruction of red corpuscles, which must be assumed to go on in the organism on a large scale At one time it was considered that the red corpuscles were destroyed in the spleen by phagocytosis Since Knisely (1936) has pointed out that the little we see of phagocytosis is either an agonal or a post mortem phenomenon, this theory can be completely discarded

The other possible method of destruction of the red corpuscles in the spleen is hæmolysis, but there is no direct evidence For this reason Mellgren's (1939) experiments on splenic hæmolysis in cats are important He found in the blood of the splenic vein, which came from the emptying of the splenic reservoir, a weak hæmoglobinæmia, which was soon much increased by continued hæmolysis in vitro, whereas in samples of blood from other parts of the vascular system this did not happen The result of Mellgren's experiments can hardly be interpreted otherwise than that in the spleen hæmolytic or, more correctly, pre hæmolytic properties are given to the blood's main components, separated in the organ, and that hæmolysis takes place when they unite

ENLARGEMENT OF

If the spleen's hæmolytic [illegible] own to be directly connected [illegible] and reservoir function, there sh[illegible] can rallel between hæmolysis and en[illegible] teen— i.e., that kind of enlargemen[illegible] to the development of granulation [illegible] r tissue but to an increased amount of b[illegible] ertainly the case to a large extent I [illegible] especially of the two physiological conditions [illegible] n erythrocytes are destroyed in increased quantities Thus the destruction of erythrocytes in the newborn infant produces the well known icterus neonatorum Akerrén (1939) has proved that an enlarged spleen is found more often at this time than during the infant's subsequent development The other state accompanied by an increased physiological hæmolysis is pregnancy, during which the spleen is enlarged in human beings and many animals because of hyperæmia (Seitz 1927), which certainly means nothing else but increased reservoir function

There is also a pathological condition in which the conception that hæmolysis is a consequence of the separator and reservoir function of the spleen may be of etiological significance—namely, hereditary hæmolytic jaundice Naegeli (1931) and others have held that the characteristic changes in the erythrocytes—i.e., spherocytosis and reduced resistance— are the primary and essential cause of the disease Others, however, especially Moulengracht (1918), have contended that the primary cause is the enlarged spleen Moulengracht believes that the reduced resistance of the red corpuscles must be due to adsorbed hæmolytic substances, normally formed in the spleen, which in hæmolytic jaundice are produced there in increased quantities Nothing has been found in the spleen in hæmolytic jaundice to contradict the assumption (Gripwall 1938) that, in this disease, it is a question of increased activity in the separation and storing of blood with consequently increased hæmolysis, as a result of the enlargement of the spleen In this way not only the anæmia but also the spherocytosis in hæmolytic jaundice can be explained

Reduction of Erythrocytes-plasma Interface in Circulating Blood

The alteration of the blood, which the spleen causes by separating the blood's two main components, can be explained in another way as due to the more or less complete removal of the erythrocytes plasma interface The relative size of this interface can also be varied in the circulating blood by two different mechanisms, of which one is easy to understand and, as Bergenhem (1939) proved, easy to demonstrate experimentally in vitro

It is a priori clear that a certain quantity of erythrocytes in the circulating blood is necessary to hinder the stabilising process of the plasma or to neutralise its effect Bergenhem's experiments on how artificial samples of blood with different proportions of erythrocytes behave when kept flowing at body temperature in vitro seem to indicate that blood with a normal number of red corpuscles remains unchanged, whereas blood with fewer corpuscles is stabilised The analogy in vivo to this experimental observation in vitro is probably the fact that one finds as a rule a lower sedimentation rate in secondary anæmia than would be expected from the composition of the plasma proteins and from the hydrodynamic effect exerted by an oligocytæmia of higher degree in increasing the sedimentation rate This was pointed out by Westergren (1924) and can now be interpreted, in my opinion, as an expression of the stabilisation of the blood in anæmia by so much adsorption of the stabilising substance formed in the blood fluid that the few corpuscles cannot neutralise it Another fact pointing in the same direction is that the red corpuscles in secondary anæmia show a relative spherocytosis (von Boros 1937, Heilmeyer 1936)

It is of interest to remember that an important reduction of the number of erythrocytes is complicated by certain disturbances in the blood's lipoid metabolism The so called bleeding lipæmia in rabbits, discovered by Boggs and Morris (1909), appears as a result of repeated blood letting, after the number of corpuscles has gone down to about 30 per cent of the normal A similar lipæmia on two

be produced by methods that cause an intravascular hæmolysis with a like reduction in the number of corpuscles It appears from Starup's (1937) experiments that lipæmia of this kind is quickly stopped by giving the anæmic animal transfusions of red corpuscles If one does not assume with Starup that the oligocytæmia produces lipæmia through diminution of the blood's capacity to carry oxygen one must hold that it is due to a relative diminution of the area of the erythrocytes-plasma interface.

DECREASED SUSPENSION STABILITY OF BLOOD

I now pass over to the other mechanism, by which the erythrocytes-plasma interface can be reduced *without* a reduction of the quantity of corpuscles. It is clear that the increase in the sedimentation-rate of the red corpuscles in pregnancy and many pathological conditions has of itself no biological importance, but it may be otherwise with the phenomenon that causes the increased sedimentation-rate—i.e., the increased rouleaux formation This is not an extravascular phenomenon The sedimentation-rate undergoes variations in the vascular system as large as those produced in vitro. I need only call to mind that large clots of fibrin in the heart and the large vessels are only found in those pathological conditions in which the sedimentation-rate is considerably higher than normal owing to intensified rouleaux formation. The different rates of intravascular sedimentation can also be shown experimentally in healthy persons, pregnant women, and patients by puncturing a superficial vein in which the blood-stream is brought to a standstill and afterwards kept vertical for some ten minutes.

More important, however, is the fact that rouleaux certainly exist in the wholly intact blood-stream. From microscopical examination of suitable skin capillaries it has long been known that there is in certain cases a granular flow—*körnige Strömung*. German authors have wrongly explained this as due to rapid intermittent contractions in the arterioles. The granular flow is simply evidence that the red corpuscles are being transported in the blood-stream in an aggregated state It is easy to convince oneself that there is a pronounced parallel between the degree of granular flow and the sedimentation-rate.

It is thus certain that the erythrocytes in patients with a high sedimentation-rate are aggregated into rouleaux, probably in a large part of the blood. This means that the total erythrocytes-plasma interface in all such cases is reduced.

Rouleaux formation produces an especially effective reduction of the erythrocytes-plasma interface. If we reckon that a red corpuscle is a short cylinder of diameter 8μ and height 2μ, each corpuscle has a surface of 150·8 sq. μ and ten free corpuscles have a surface of 1508 sq. μ If, on the other hand, these ten corpuscles build a rouleau, their total free surface decreases to 603 sq. μ It seems likely that the disk-form of the red corpuscles is biologically important in that it makes possible large variations in the size of the erythrocytes-plasma interface It need hardly be pointed out that the erythrocytes-plasma interface, decreased through rouleaux formation, is not for any length of time formed by the same external parts of the same corpuscles The rouleaux are continually being broken and re-formed, but this does not prevent the interface at each moment from being of a certain size, which (with equal numbers of corpuscles of the same size) depends only on the degree of the blood's suspension stability.

When the erythrocytes-plasma interface decreases in pregnancy and in infection, it can be postulated, in my opinion, that large parts of the circulating blood are exposed to somewhat the same influence as the reservoir blood of the spleen I believe, therefore, that enlargement of the spleen and the reduction of the blood's suspension stability are related reactions, whose simultaneous appearance in pregnancy and in infections is not a mere coincidence

The intensified rouleaux formation, which is caused by the increase of the fibrinogen and serum-globulin fractions of the plasma (Fåhræus 1921) promotes the sedimentation of the red corpuscles to such a degree that any influence exerted by the stabilisation process, as a consequence of the diminution of the erythrocytes-plasma interface, is very probably masked and difficult to elucidate

One may ask if this second way of reducing the erythrocytes-plasma interface—i.e., rouleaux formation—is, like the above-mentioned oligocytæmia, also connected with similar disturbances of lipoid metabolism. This is clearly not the general rule, for in many infections which show a higher sedimentation rate there is no lipæmia However, *special factors* may come into play, especially fever, which, according to Ewert's (1935) experiments, considerably reduces the level of blood-cholesterol; but in fever-free conditions with reduced suspension stability it is tempting to draw the above analogy. Nephrosis is a fever-free condition with usually a very high sedimentation-rate and pronounced lipæmia During pregnancy a lipæmia appears, which shows a pronounced parallel with the sedimentation-rate. Concerning the cause of lipæmia in pregnancy there are, as Boyd (1934) pointed out, no less than fifteen different theories Herewith I put forward the sixteenth: that the alteration of the fat-metabolism of the blood during pregnancy is due to a decrease of the erythrocytes-plasma interface, which is very probably a significant manifestation of the decreased suspension stability of the blood.

Summary

(1) Erythrocytes and plasma, kept separate from each other, undergo—by what is called the stabilisation process—changes, which as regards the erythrocytes consist in decreased rouleaux formation and spherocytosis—alterations in direction of hæmolysis—and as regards the plasma in the formation of lysolecithin by a serum-lecithinase similar to that in cobra venom

(2) These changes take place in the spleen—the separator of the blood—at least as regards the erythrocytes, which are kept for long periods deplasmatised in the venous sinuses of the organ (Knisely 1936), but probably also as regards the plasma, and hæmolysis takes place when separated blood components reunite in the splenic vein

(3) The fact that the circulating blood maintains its properties depends on the fact that the stabilisation process in the erythrocytes is prevented or its effect neutralised by the plasma and vice versa —an interaction which must be located at the erythrocytes-plasma interface

(4) The area of this interface may be diminished not only in the spleen but also in the circulating blood, with effects upon its fat-metabolism. This may occur either by the reduction of the number of erythrocytes or by increased rouleaux formation—the intravascular phenomenon which causes the increase sedimentation-rate in diseases and pregnancy.

"INFLUENZAL" MENINGITIS
TREATED WITH M & B 693
REPORT OF TWO CASES

By E H Roche, M C, M D Lond, F R A C P
PHYSICIAN TO THE AUCKLAND HOSPITAL, NEW ZEALAND AND
J E Caughey, M D N Z, M R C P, F R A C P
ASSISTANT PHYSICIAN TO THE HOSPITAL

The treatment of "influenzal" meningitis with drugs of the sulphonamide group has been reported by Teggart (1938), Young and Moore (1938), and Taylor (1938) In two cases recovery followed We can trace no record of "influenzal" meningitis treated with M & B 693, which prompts us to report the following two cases

CASE RECORDS

Case 1.—A boy, aged 17 months, was admitted to the Auckland Hospital on March 2, 1939 For three weeks before admission he was somewhat fretful, but this was attributed to teething Two days before admission there was a definite history of exposure to chill, and the next day malaise, cough, and conjunctivitis were noted

On admission the temperature was 103° F, pulse-rate 160, and respiration-rate 71 (sleeping) The only signs present were coryza, conjunctivitis, and scattered rales throughout both lungs, suggesting acute influenza with incipient pneumonia On the basis of this diagnosis treatment with M & B 693 was promptly instituted

When seen by one of us (E H R) two days after admission (fourth day of illness), the temperature was 104° F, pulse-rate 170, respiration-rate 70, and he looked seriously ill Conjunctivitis was still present, but there were no signs of bronchitis or pneumonia The ears were normal and the throat only slightly injected There was no rigidity of neck or back and no Kernig The only other features noted were undue brightness of the eyes and general irritability There were no definite signs of meningitis, but in view of the irritability and the unexplained ill appearance of the child a lumbar puncture was done forthwith The cerebrospinal fluid (C S F) was under increased pressure and turbid There was a definite increase of globulin The films from the centrifuged deposit showed pus and a few gram negative bacilli These were mainly intracellular, as many as six bacilli being found within one polymorph cell Cultures grew *Bacillus influenzæ*

Treatment and progress.—On the second day of illness—i.e., on admission—M & B 693 was exhibited, the total for the first twenty-four hours being 2·5 g, of which probably 0·5 g was vomited On the third day, because of gastric intolerance, the dose was reduced to a total of 1·75 g, but vomiting still continued On the fourth day, after the first lumbar puncture, it was realised that much larger doses would be needed, and in view of the importance of nutrition further vomiting could not be permitted The drug was therefore suspended in sterile olive oil (1 tablet to 2·5 c.cm.) and given by intramuscular and subcutaneous injections mainly into the anterior abdominal wall The methods of suspension in water and in normal saline, described respectively by Somers (1939) and Bryant and Tairman (1939) were not then known to us The total dose on the fourth day was 1·5 g

On the fifth day 3 g of M & B 693 was injected, and the C S F was still turbid On the sixth day 1·75 g was given, the C S F was much clearer and cultures were sterile The haemoglobin was 9·05 g per 100 c.cm., and the leucocyte count 13,700 A small intravenous transfusion of 4 oz of blood with 4 oz of saline was then given On the seventh day the haemoglobin had risen to 12·1 g per 100 c.cm. and the leucocyte count to 23,000 In view of this good result a further 6 oz of blood with 7 oz of saline was then given The child was still very irritable, and a definite Kernig's sign and neck rigidity had developed On the seventh and eighth days a mistake was made in the dosage of M & B 693, so that on each of these days only 0·13 g was given This error was rectified, however, and during the next five days the total dosage amounted to 9·5 g

On the thirteenth day Dr C R Burns saw the case in consultation, the point at issue being the continuance or not of administration of M & B 693 On the one hand, the C S F had been sterile for seven days, and the injections were beginning to distress the child, on the other hand, the temperature was still 101·6° F and pulse-rate 156, and definite signs of meningeal irritation (Kernig's sign and rigidity of the neck and back) were still present The total dosage of the drug, allowing for losses by vomiting, had been 18 g.—i.e., just over 0·75 g per lb of body-weight In view of the big dosage and its long duration (twelve days) and the probable further absorption from the oily suspension during the next few days it was decided to stop the administration of M & B 693 and to watch developments

On the fifteenth day the C S F was clear and colourless and contained only twelve cells per c.mm On the twentieth day the child was sitting up, with a normal temperature, and on the twenty-seventh day he was beginning to stand There were no physical signs, and the C S F was normal except for a slight increase of pressure On the thirty-first day he contracted an upper respiratory infection with a spike of temperature, but this quickly subsided, and he was discharged completely well on the forty-second day When seen two months later the child was normal in every respect

Summary of case 1.—A boy, aged 17 months, whose illness was diagnosed on the second day as severe influenza and on the fourth as influenzal meningitis Treatment with M & B 693 was begun on the second day and continued without interruption till the thirteenth day The drug was administered orally for the first two days and subsequently by injection of an oily suspension The total quantity given was 18 g (0·75 g per lb of body weight) Periodic examination of the haemoglobin and leucocytes in the blood was made, and two blood transfusions were given Lumbar puncture for the purpose of drainage was performed daily for three days during the period of maximal dosage of the drug and subsequently for diagnostic purposes on two

occasions The C S F. was sterile on the sixth day of the illness, and thereafter the patient made a complete and uninterrupted recovery (see fig 1).

CASE 2.—A girl, aged 12 years, first complained of frontal headache on March 19, 1939. On the following day she vomited several times and the headache became severe. On the 21st her temperature was 104° F., and she complained of stiffness at the back of her neck, and any movement induced headache. These symptoms persisted, and when she was seen on the 22nd by one of us (J. E. C.) the pulse-rate was 112, temperature 104° F., respiration-rate 20, and she was in a state of toxic delirium. She was confused and disorientated as to time and place and lay curled up in bed with knees drawn up and head somewhat extended The ocular fundi were normal, and the pupils were 6 mm., equal, and regular, and reacted briskly to light. Ocular movements were full in all directions, and there was no diplopia, nystagmus, or strabismus. The fifth cranial nerve presented no abnormalities, and there was no weakness of the facial muscles. The remaining cranial nerves presented no abnormalities. The deep reflexes were present and equal The tone of the lower extremities was moderately increased, the power was reduced, and coordination was unimpaired. The deep reflexes were brisk and equal, the plantar responses being flexor. There was definite rigidity of the posterior cervical muscles. The back was held rigidly, and the patient resented any attempt at flexion Kernig's sign was obvious in both lower extremities. The ear-drums were normal, and the throat was moderately congested.

Lumbar puncture revealed a slightly turbid fluid with an opalescent appearance and under a pressure of 240 mm The fluid contained many pus cells and gram-negative bacilli, and the globulin was increased. On culture there was an abundant growth of *B. influenzæ* The urine contained a small amount of albumin but no pus or organisms

Treatment and progress—On March 22 (the fourth day of the illness) meningitis was diagnosed and treatment with M. & B. 693 begun immediately Four tablets (2 g.) were given at 5 30 P.M. and repeated at 8 30 P.M., and thereafter two tablets were ordered two-hourly. In the first seven hours the patient received 6 g. of M & B. 693, and at this stage there was no intolerance to the drug. During the first night she was restless, delirious, and incontinent of urine.

On the morning of the 23rd she was clearer mentally. The temperature was 102 4° F., pulse-rate 94. The administration of M. & B. 693 was continued in the same dosage (two tablets two-hourly) By 9 P.M the temperature had fallen to 98° F., pulse-rate 84. Twenty-four tablets were given in the twenty-four hours. On the 24th at 5 A.M. the temperature was 97 8° F., and pulse-rate 72, but during the morning the patient became restless, and the temperature rose to 100° F. During this day the tablets were reduced to two four-hourly (twelve tablets in the day) Lumbar puncture showed a turbid opalescent fluid under pressure of 180 mm and 30 c cm. of spinal fluid was removed. A blood-count gave the following result:

Red cells	5,470,000	Polymorphs	62 %
White cells	13,150	Lymphocytes	30 %
Hæmoglobin	96 %	Monocytes	8 %
Colour index	0 89		

On March 25th her mental condition had improved, and she was taking fluids well. There was moderate cyanosis. The two tablets of M. & B. 693 were given four-hourly (twelve tablets in the day) The temperature was 101° F. at 7 P.M., and 15 c cm. of opalescent fluid was removed by lumbar puncture. On the 26th her condition had improved, nourishing drinks were being taken well, and her diet was increased. The temperature during the day fell from 101° F. to 99 2° F. M. & B. 693 was given as before (twelve tablets in the twenty-four hours).

On March 27th the patient complained of backache and headache, and the temperature rose to 102° F. It was decided to do a further lumbar puncture to relieve the headache, and 30 c.cm. of turbid opalescent fluid was removed and the headache somewhat relieved. The fluid showed only a moderate number of pus cells and a few gram-negative bacilli, most of them lying within the polymorphs. The administration of M. & B. 693 was continued in the same dosage (twelve tablets in the twenty-four hours) A blood-count showed red cells 4,620,000 hæmoglobin 82 per cent (12 g. per 100 c cm.), colour-index 0 9, and leucocytes 18,000.

On the 28th the temperature fell to normal. The administration of M. & B. 693 was continued for sixteen hours (eight tablets). At this stage the patient was much improved. She was moderately cyanosed In six days she had had 47 g. (ninety-four tablets) of M. & B. 693, had shown remarkable tolerance, and had not vomited Our lack of facilities for the estimation of the content of the drug in the blood and C S F is the main justification for such massive dosage in this case. The drug was discontinued at this stage

On March 29 lumbar puncture showed turbid fluid with an obvious increase of globulin. Films of the centrifuged deposits contained pus cells and a few gram-negative bacilli. Culture produced an abundant growth of *B influenzæ* It was decided at this stage to give another salt of the sulphonamide group. Proseptasine was given (two tablets four hourly for six doses) On the 30th the patient had a very comfortable day, but the temperature rose to 101° F. and the pulse-rate to 112. Proseptasine was discontinued after 6 g. had been given. On the 31st she was quieter and very drowsy. Temperature 103° F., pulse-rate 116 She was troubled with the passage of very offensive flatus

On April 1 the temperature was 102° F., and, since the C S.F. was still turbid and contained gram-negative bacilli and pus cells, it was decided to administer M & B 693 in big doses. Between 3 30 P.M. and midnight twelve tablets were given. The

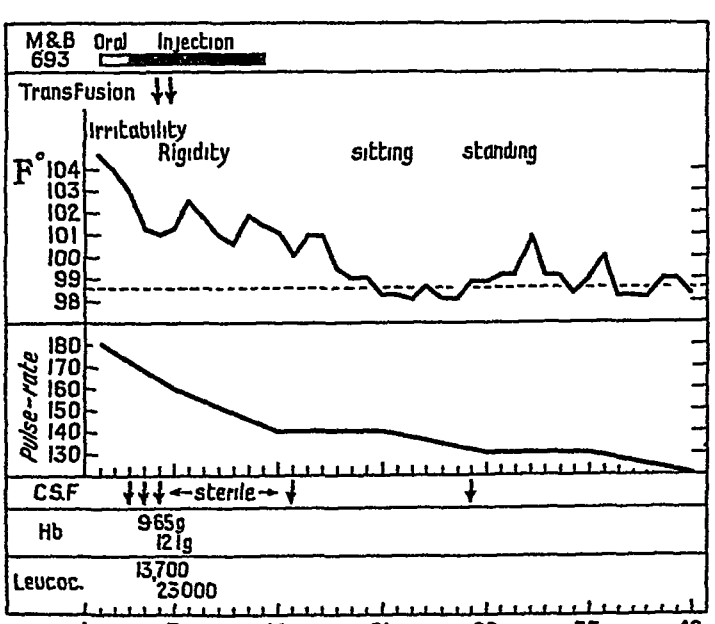

FIG. 1—Progress of case 1. C S F. arrows = lumbar puncture.

patient became moderately cyanosed and restless and vomited during the night. This was the first time vomiting had occurred since the start of treatment. At this stage the case was seen by Dr. L. Ludbrook, and it was decided to give a blood transfusion (200 c.cm.) and 5 c.cm. of the patient's father's serum intrathecally to add complement to the C.S.F.

M. & B. 693 12 g. was given on the 3rd and 6 g. on the 4th, and then administration of the drug was discontinued. Lumbar puncture showed the fluid to be under pressure of 140 mm. It was slightly turbid and contained an increased amount of globulin (334 pus cells per c.mm.), but no organisms were seen, and cultures were sterile after forty-eight hours. A blood-count gave the following result —

Red cells	3,410,000
White cells	11,150
Hæmoglobin	68%
Colour-index	1
Polymorphs	70%
Lymphocytes	24%
Monocytes	4%
Eosinophils	2%

On the 5th the temperature rose to 102° F. A blood transfusion of 350 c.cm. was given. Lumbar puncture on the 6th revealed a turbid fluid under pressure of 100 mm. It contained pus, increased globulin, and an occasional gram-negative bacillus. The temperature was 103° F. and the pulse-rate 110. On the 7th and 8th the temperature fell to 99° F. but rose again to 101° F. on the 9th. It was decided to administer M. & B. 693 once more. During the day twenty-four tablets were given, but the patient became moderately cyanosed, cold, and very nauseated. During the day she vomited four times. A mixture of bismuth and soda was given with the tablets, but in spite of this she continued to vomit at intervals until midnight, so administration of the drug was discontinued.

For the following four days the temperature was normal. The pulse-rate was 80–110. During this time the patient took nourishment well. On the 15th, 16th, and 17th there was a slight rise of temperature to 100° F. The blood count on the 17th gave the following results —

Red cells	4,100,000	Polymorphs	58%
White cells	8300	Lymphocytes	38%
Hæmoglobin	85%	Monocytes	4%
Colour-index	1·03		

The temperature continued to swing daily to 100–101° F., and on the 21st it was decided to give more M. & B. 693 (two tablets six hourly) for the C.S.F. still contained an increased amount of cells, and on culture there were a few colonies of *B. influenzæ*. By the 24th the temperature had fallen to normal, although the pulse-rate remained high (100–120).

From this time the patient made an uninterrupted recovery. The pulse-rate fell to 70–80, and on May 5 there was no rigidity of the neck muscles and there was very little stiffness of the hamstring muscles and back muscles. The patient was bright and eating well. The C.S.F. was at a pressure of 110 mm. and was colourless. There was slight increase of globulin. No organisms were seen, and cultures were sterile. The patient was discharged on the 13th, and since that date has rapidly improved and is gaining weight. All rigidity of the back and legs has disappeared, and she has shown no evidence of sequelæ.

Summary of case 2.—A girl aged 12, whose illness was diagnosed on the fourth day as influenzal meningitis, was treated with M. & B. 693 (106 g.) and proseptasine (6 g.), which were exhibited in five "bursts" of treatment. The treatment was controlled by periodic blood counts and examinations of the C.S.F. Gastric tolerance to the drug at first was good, but subsequently vomiting occurred frequently. Blood transfusion was used twice, and on one occasion human serum was added to the C.S.F. in an attempt to supply complement. The patient made a complete recovery. On the forty-sixth day of the illness the temperature and pulse-rate were normal, and the C.S.F. was sterile (*see fig. 2*).

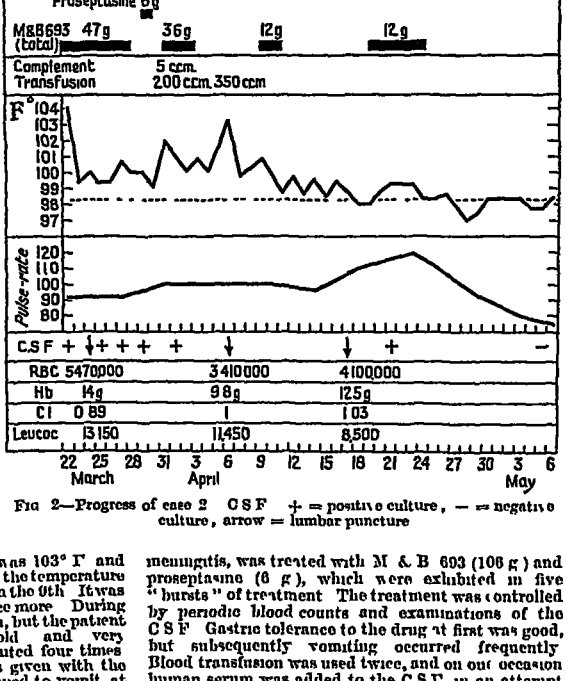

FIG. 2—Progress of case 2. C.S.F. + = positive culture, − = negative culture, arrow = lumbar puncture.

COMMENTS

Lumbar puncture.—The therapeutic value of frequent lumbar puncture has been questioned by Banks (1938) and by McAlpine and Thomas (1939) in discussing a case of pneumococcal meningitis. These workers believed that excessive drainage of the C.S.F. might be a factor in promoting the formation of adhesions round the lower brain stem with subsequent hydrocephalus, and that it lowered the concentration of the chemotherapeutic drug and so reduced its effect. If the pressure is reduced to such an extent as to allow the base of the brain to press upon the meninges surrounding the foramen magnum, the danger of subsequent adhesions seems to be very real, if, however the pressure is maintained above the normal level we suggest that this danger is very small. The effect of the lumbar puncture on the concentration of any drug in the C.S.F. must depend on whether the drug is still being administered in full doses and on its maximal concentration maintained in the blood. We suggest that during the period of administration of M. & B. 693 any C.S.F. withdrawn will be quickly replaced by fresh fluid containing the same concentration of the drug, and in that case the removal of bacilli and toxins from the intrathecal space must do good. When, however,

the administration of the drug has been stopped, lumbar puncture should be avoided, except for purely diagnostic purposes, and then only a minimal quantity of fluid should be withdrawn.

Transfusion and complement—In both of our cases a blood-transfusion was given twice, and we are satisfied that this played a part in the recovery of these two patients. We believe the value of transfusion to lie chiefly in the treatment of the hæmolytic anæmia induced by the sulphonamides It might be thought that the transfusion of fresh blood would add complement to the C S F However, the work of Finland et al. (1938) suggests that the C.S F. contains no complement, so that by adding complement to the blood-stream we can only assist during the septicæmic stage of the disease. In view of Finland's findings, in case 2 we gave human serum intrathecally in an effort to add complement McIntosh and Whitby's (1939) work suggests that the sulphonamides act by "neutralisation of some metabolic function or enzymatic activity of the organisms" and do not actively destroy them, so that by adding complement we hoped to aid the natural immunity of the body which must go hand in hand with the action of the sulphonamides We were unable to assess the value of intrathecal complement, for its administration coincided with treatment with the drug and with the first transfusion.

M & B. 693—In view of the almost uniformly fatal course of influenzal meningitis in children, the recovery of two consecutive patients, one of whom was only 17 months old, cannot reasonably be ascribed to coincidence Apart from lumbar puncture and blood-transfusion, whose inadequacy has been so conclusively proved in the past, the only treatment common to both cases was the administration of M. & B. 693 These considerations, together with the impressions gained from observation of the cases, compel us to believe that the good results obtained were pre-eminently due to this drug

We wish to thank Dr W. Gilmour and Dr. E. Fowler for kindly performing the pathological investigation, and Dr. L Ludbrook and Dr. C. R. Burns, with whom we consulted frequently.

"... The value of examinations as a test of knowledge is debatable; but it seems probable that much of the criticism levelled at the examination system should be directed, more properly, against unskilled examiners, who bring the system into disrepute by setting stupid papers and asking ambiguous questions A well-conducted examination is a good test of knowledge and, what is even more important, constitutes a potent stimulus to effort on the part of the examinee It is therefore desirable to hold an examination at the end of the first and of the second year of the course, though the system might be strengthened by the furnishing of reports from demonstrators in charge of the various groups of students upon the work done by each man during the year Due consideration should be given by the examiners to these reports, which would be of special value in the examination at the end of the first year, if, as has been urged, this should be regarded as a means for elimination of the unfit."—Sir ALAN NEWTON, *Med J Aust* July 15, 1939, 91.

VALVULAR PNEUMOTHORAX

TREATED BY MECHANICAL VALVE AND OBLITERATIVE PLEURISY

BY F. G. CHANDLER, M D. Camb, F.R C P.
PHYSICIAN TO ST BARTHOLOMEW'S HOSPITAL, SENIOR PHYSICIAN TO THE LONDON CHEST HOSPITAL

AN analysis made by Perry (1939) of cases of spontaneous pneumothorax shows that 70 per cent. are non-tuberculous and I have the impression that my experience confirms this preponderance of non-tuberculous cases Nevertheless, before assuming that the perforation is of non-tuberculous origin, every investigation must be made, including an inquiry into preceding malaise, loss of weight, hæmoptysis, examination of sputum and fæces for tubercle bacilli, temperature at 6.30 P M, sedimentation-rate, and a careful scrutiny of the radiogram.

One principle of the treatment of non-tuberculous spontaneous pneumothorax, where special treatment is needed, (*a*) because of a persisting simple or valve perforation or (*b*) because of recurrent attacks, is the production of an aseptic irritation of the pleura and a small fibrinous effusion to start obliterative pleurisy The other principle, applicable to high-pressure spontaneous pneumothorax, is a simple valve mechanism This article describes the combination of these two principles in the management of high-pressure pneumothorax.

INDUCED OBLITERATIVE PLEURISY

The re-expansion of the collapsed lung, which can be obtained by the injection of a 5 per cent solution of Gomenol in olive oil into the pleural cavity and by the consequent induction of obliterative pleurisy in spontaneous pneumothorax with a persistent perforation, has already been described (Chandler, 1938).

Gomenol is the irritant used, because its action on the pleura is well known It is safe if used cautiously. There is no exact dosage. Not much must be given at first, otherwise the reaction may be too severe; nor must the dose be increased too gradually, lest the pleura become accustomed to the oil and so not react. The suggested dosage is 2 c cm of a 2 per cent solution, followed by 5 c cm. of a 5 per cent. solution, 10 c.cm of a 10 per cent solution, and 20 c.cm. of a 20 per cent. solution. If the pleura does not then react, sodium morrhuate or else iodine might be used, but I have no experience of the use of these in the pleural cavity in spontaneous pneumothorax.

Induced obliterative pleurisy has been employed in a case of recurrent spontaneous pneumothorax.

CASE 1.—A man, aged 30, was referred to me by Dr. R. R. Fells after having had his tenth spontaneous pneumothorax. They had developed on each side at different times, being brought on by the most trivial action. When I first saw him he had a left-sided pneumothorax which was almost absorbed. I therefore advised that obliterative pleurisy should be induced on the next occasion to prevent further attacks.

Within eight weeks he had a spontaneous pneumothorax on the right side and was admitted to the London Chest Hospital. Thoracoscopy to discover the cause of the ruptures showed no bullæ of any kind on the anterior and lateral surfaces of the lung, these being the only parts visible. The lung was very pink, and there were parallel horizontal lines of pigment running regularly over the visceral pleura, as though the lung were unnaturally voluminous and, when uncollapsed, pressed unduly against the ribs

and intercostal spaces Through the thoracoscopic cannula 5 c cm of a 10 per cent solution of gomenol in olive oil was injected and 1800 c cm of air withdrawn

The same afternoon the patient experienced pain at the right base and a temperature of 99° F , and the next day some pain and tenderness, with no change of temperature On the following day the pain had disappeared, the temperature was normal, and some fluid had appeared The next day the fluid slightly increased, and thenceforth the lung steadily and completely re-expanded

It is impossible to say yet whether a permanent result has been obtained nor how firm an adhesion between the two layers of the pleura is produced by this method One can only hope that no further spontaneous pneumothorax will develop on the right side If and when the next left sided pneumothorax appears, the treatment will be repeated on that side

HIGH PRESSURE PNEUMOTHORAX WITH VALVULAR TEAR

The utmost distress to the patient and the greatest anxiety in its management may be caused by high pressure pneumothorax with a valvular opening It may prove fatal Effective removal of the intrapleural air does not necessarily make the two layers of pleura adhere, and aseptic pleural irritation will not alone avail, for the rupture, acting as a one way valve, keeps the two layers of the pleura apart With every inspiration air comes out through the valvular tear into the pleura , with every expiration the valve closes and the air is imprisoned in the pleural cavity With the continued repetition of these alternate events the lung is kept completely collapsed, the mediastinum is grossly displaced, and the visceral and parietal layers of pleura cannot approximate and adhere together The two methods—the induction of obliterative pleurisy and the use of a valve mechanism—therefore must be used simultaneously A valve can be made with a thin rubber fingerstall in the closed end of which a slit has been made The valve in the fingerstall acts in exactly the opposite way to the valvular opening in the lung, it allows more air to escape into the atmosphere with each expiration than escapes from the lung into the pleural cavity with each inspiration, because the slit in the fingerstall can be made bigger than any probable tear in the lung, with the result that there *is no high positive* pressure in the pleural cavity In a short time more air escapes through the fingerstall than escapes through the tear in the lung , so the pleural space is almost emptied of air and the pleural layers can come together, whereupon the induction of obliterative pleurisy may cause them to adhere together

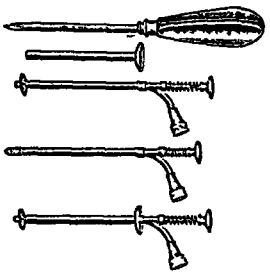

FIG 1—Mr Zachary Cope's self retaining cannula

The following case illustrates the points It is the first time that the Cope (1939) self retaining cannula (fig 1) has been used for this purpose *Canules à demeurer* were used over a century ago, especially between 1825 and 1845, for pleural effusions and empyemas, flaps of goldbeater's skin being used instead of rubber to form the valve at the opening of the cannula , so the conception of the valve mechanism is not new, but I think that the combination of methods is new

CASE 2 —On April 20, 1939, I was asked by Dr H J S Morton to see a man, aged 58, who on getting out of bed one morning had felt a severe pain in the right chest with breathlessness He had had to sit on the side of the bed for a time, but later he had gone down to breakfast He had remained in the house all day but on going to bed at night had suddenly become more breathless and cyanosed

The classical signs of spontaneous pneumothorax were found, and the patient was admitted to the London Chest Hospital, where radiography showed the heart considerably displaced to the left and practically complete collapse of the right lung (fig 2) The patient was distressed, very cyanosed, and dyspnoeic

On the 21st 2000 c cm of air was withdrawn, with only transitory relief, the pressures returning to 0 + 10 cm of water after two minutes More air was withdrawn later, with the same result

On the 23th a pneumothorax refill needle was inserted into the pleural cavity in the second space anteriorly, just external to the midclavicular line To the proximal end of the needle was tied a thin rubber fingerstall in the closed end of which a slit had been made At the same time 2 c cm of a 2 per cent solution of gomenol in olive oil was injected into the pleural cavity There was no reaction The valve acted excellently, and the heart returned to its normal position , but, owing to movements and cough the end of the needle worked out of the pleural cavity into the chest wall and surgical emphysema developed

On the 29th a long extrapleural pneumothorax-refill needle was therefore used This also became

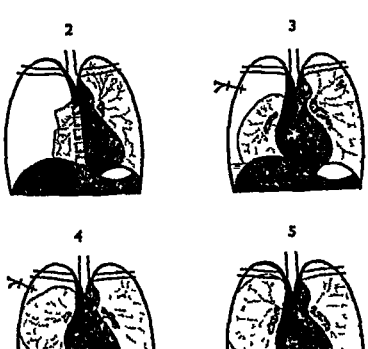

FIG 2 (case 2)—High pressure spontaneous pneumothorax with valvular tear, showing practically complete collapse of the right lung displacement of the heart towards the left side and partly beyond the spine, and displacement of the trachea

FIGS 3 and 4 (case 2)—Re-expansion of the right lung after the insertion of the self retaining cannula and the injection of gomenol

FIG 5 (case 2)—A month after the insertion of the cannula and the injection of gomenol, showing the right lung almost completely re-expanded and only a small residual pneumothorax

displaced, causing more surgical emphysema; moreover it caused pain and became blocked.

On May 2 Cope's self-retaining cannula was used, the fingerstall being tied over the curved outer end. At the same time 10 c.cm. of a 10 per cent. solution of gomenol in olive oil was injected into the pleural cavity. The temperature did not rise, but there was some malaise and some fluid appeared.

On the 3rd the fluid increased and the patient had slight nausea By the 13th the fluid had risen to the ninth rib posteriorly, and the lung was adhering to the diaphragm and approaching the chest wall.

From this time the lung began to re-expand steadily and became attached to the chest wall (figs. 3 and 4), and by the 12th fluid began to come through the cannula. This was therefore withdrawn on this day, with some anxiety lest the valvular opening should not have healed sufficiently firmly and the lung be stripped away from the chest wall. The patient was watched carefully, however, and nothing untoward happened. By the 18th the lung was touching the chest wall up to the third space in the midaxillary line, and the dome of the lung reached as high as the fourth rib posteriorly.

On May 21 the patient was allowed up, feeling and looking well, with the heart in the normal position Radiography on June 1 showed the lung to be almost completely re-expanded, with a small residual pneumothorax in the uppermost part of the pleural cavity (fig. 5).

The Cope self-retaining cannula acted perfectly. It remained in position eleven days without becoming displaced Occasionally fibrin blocked the lumen, but it was a very simple matter to remove the inner cannula, clean it, and replace it, a spigot being placed in the outer cannula meanwhile

The most strict aseptic and antiseptic precautions were taken The skin was kept clean with iodine and spirit and with acriflavine alternately, and the skin and the instrument were covered so far as possible with sterile dressings, leaving the fingerstall free. There was no infection of the fluid, the cannula track, or the skin. It was realised that infection was possible, but it was a risk that had to be taken. I believe that with care of every detail infection can probably be prevented

Theoretically the self-retaining rubber catheter might be used, but there are many objections to this: collapsibility, difficulty of cleaning if blocked, and difficulty with removal and reinsertion. With the Cope self-retaining metal cannula there are no such difficulties It might be possible to use a self-retaining rubber catheter passed through a cannula, the latter being retained permanently in position; but the catheter and cannula would have to be kept very small, and I doubt if the flange of a catheter so small would be strong enough to make it truly self-retaining. Nevertheless, in an emergency, if the Cope self-retaining cannula were not available, I believe it would be good practice to insert a stout self-retaining intercostal catheter with a fingerstall valve tied to the end This might be the best method in traumatic pneumothorax, especially under war conditions.

SUMMARY

(1) The value of induced obliterative pleurisy in non-tuberculous spontaneous pneumothorax, previously reported in a case with a persistent perforation (Chandler 1938), is reaffirmed.

(2) A case of recurrent spontaneous pneumothorax is described in which obliterative pleurisy was induced.

(3) In high-pressure spontaneous pneumothorax in a valvular rupture of the lung it is possible to bring about the conditions suitable for the induction of obliterative pleurisy by combining this method with the use of the Zachary Cope self-retaining cannula fitted with a mechanical valve (a fingerstall with a slit). A case is described in which this was done.

IRON ADMINISTRATION AND HÆMOGLOBIN LEVELS DURING PREGNANCY

BY E. M. WIDDOWSON, B.Sc., Ph D.

(From the Department of Medicine, University of Cambridge)

IT has been recognised for some time that the blood of normal non-pregnant women tends to contain less hæmoglobin than that of men (Price-Jones 1931, Widdowson and McCance 1936), and it has been suggested, in explanation of this fact, that women often have a mild but really pathological anæmia. To test this Widdowson and McCance (1936) gave iron to a group of normal men and women and observed their hæmoglobin levels The women's hæmoglobin tended to rise and approached the men's level; the men's hæmoglobin did not change This observation has been confirmed (Barer 1937, Sankaran and Rajagopal 1938), and from all we know of the metabolism of iron we may confidently attribute the rise to the absorption of inorganic iron. It has subsequently been found, however, that women's hæmoglobin persists at the higher levels only so long as iron continues to be administered (Barer 1937, Sankaran and Rajagopal 1938) This is a very important extension of the original observation, because iron once absorbed is not apparently re-excreted (McCance and Widdowson 1937, Widdowson and McCance 1937, McCance and Widdowson 1938) Why, therefore, should the hæmoglobin fall when the body probably contains more iron than it did while the hæmoglobin was rising? Why should it fall to a level lower than men's average level when the body contains far more iron than the average man's? Steenbock et al (1936) noted that differentiation in the storage of iron in male and female rats appeared with sexual maturity. Castration of the female led to decreased storage Injection of the follicular hormone into sexually immature female rats promoted greater storage than in the litter-mate controls. This is no new idea, for Bunge (1880) suggested that from puberty onwards the female stored reserves of iron for future needs of reproduction.

Children may respond to the administration of iron in the same way as adults. Mackay (1931) has recorded the prevalence of an anæmia at certain ages which can be cured with iron. It has also been noted that, if the administration of iron is stopped, the anæmia tends to recur (Josephs 1939, Mackay 1939).

The experiment here described was undertaken to obtain further evidence on this matter. It is well known that pregnant women are often anæmic, and, although probably the cause is not the same in all cases, it is generally admitted that the administration of iron will prevent the fall of hæmoglobin. It was therefore decided to study the hæmoglobin levels of pregnant

women before, during, and after periods of therapeutic medication with iron

INVESTIGATION

Hæmoglobin determinations were made by the Haldane method on 100 women, all of whom were 20 weeks' pregnant or less, attending the antenatal department of King's College Hospital, London. The determinations were repeated a month later. Then half the women (those attending on Wednesdays) were prescribed 1000 mg. of iron, as ferric ammonium citrate or ferrum redactum, daily for six weeks. The level of hæmoglobin in the capillary blood was determined at fortnightly intervals. The administration of iron was then stopped and the hæmoglobin estimated fortnightly until a week after delivery. The other women (attending on Tuesdays) were given no medicine, and their hæmoglobin levels were observed at monthly intervals until delivery and again a week later. In both groups an estimation was always made within twenty four hours after delivery. All determinations were made in duplicate by the same person, who did not know, while making the estimation, to whom any sample of blood belonged. At the end of the experiment it was decided not to consider (1) women whose babies were born before the thirty sixth week, (2) women who had taken the last dose of iron within eight weeks of delivery, and (3) women in the experimental group who had not taken the prescribed iron. After these omissions 31 women were left in the "iron" group and 44 in the control group.

RESULTS

The presentation of the results is complicated by the difficulty—common to so much biological work—that, whatever the stimulus, no two individuals ever react in exactly the same way. Averaging the results is unsatisfactory in that it tends to obscure exceptional individuals who may be giving important information. The policy adopted has been to mention the exceptional cases, to give the results of a few typical individuals of both the control and the experimental groups, and to give the averaged results of both groups.

In the control series some women's hæmoglobin did not fall with the progress of pregnancy, and a very few women showed a slight rise. The characteristic response was a tendency to fall steadily throughout pregnancy and to rise sharply after delivery (figs 1 and 3).

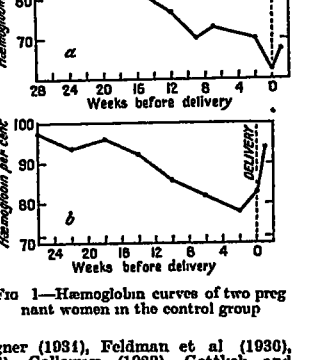

FIG 1—Hæmoglobin curves of two pregnant women in the control group

These results are in keeping with the work of Adair, Dieckmann, and Grant (1936), Bethell (1936), Bland, Goldstein, and First (1930), Boycott (1936), Dieckmann and Wegner (1934), Feldman et al (1936), Fullerton (1936), Galloway (1929), Gottlieb and Gottlieb (1930), Reid and Mackintosh (1937), Strauss and Castle (1932), Toverud (1935) and require no further comment.

The cause of the fall, although possibly in some cases the result of a true deficiency of iron (Davidson et al 1933, Mackay 1935), is probably largely due to a rise in the volume of plasma unaccompanied by a corresponding rise in the number of circulating red blood cells (Boycott 1936, Dieckmann and Wegner 1934, Feldman et al 1936, Strauss and Castle 1932, Thomson et al 1938). The phenomenon is not confined to humans (Beard and Myers 1933, Van Donk et al 1934).

The responses of the experimental group are much more complicated than those of the control because, besides the effects of pregnancy and delivery common to both groups, two further stimuli were in operation (1) the administration of iron, and (2) the cessation of its administration. The response to iron was not an instantaneous increase in all the women's hæmoglobin concentrations. A few of the hæmoglobin curves continued to fall, as though iron had not been given at all (fig. 2a); several showed a break in the fall but no real rise within the six weeks of medication (fig. 2b), and most of them rose, some very much more than others (figs. 2c and d). The cessation of administration of iron led almost always to a fall in the hæmoglobin level of those women in whom its administration had initiated a rise. Some of the women gave an indeterminate a response to the

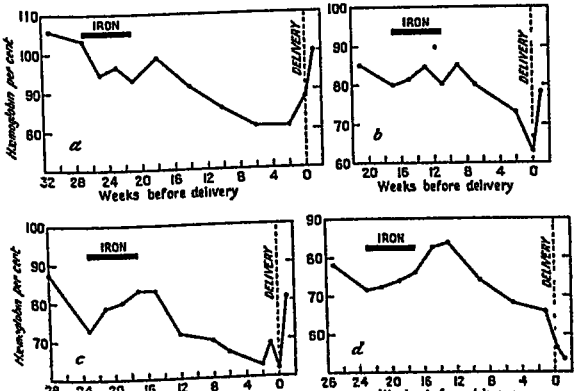

FIG 2—Hæmoglobin curves of four pregnant women in the experimental group, showing various types of response to the administration of iron: (a) continued fall in spite of iron, (b) a break in the fall but no real rise, (c) and (d) rises

removal of iron as they had given to its administration. The fall in hæmoglobin which manifested itself after the medication with iron had been stopped was not arrested in most cases until delivery. Fig 3 shows the averaged results for both the control and the experimental groups In preparing the averaged curve for the experimental group a difficulty arose in that the women started taking the iron at different stages of pregnancy. Thus it was necessary in constructing the dotted portion of the curve to average "weeks before delivery" as well as hæmoglobin values. The average time at which the first hæmoglobin estimation was made was twenty-four weeks before delivery, and the average hæmoglobin level at this stage was 93 per cent Similarly medication with iron was started, on average, at twenty weeks before delivery and finished at fourteen weeks The mean hæmoglobin levels at these times were 87·4 per cent. and 89 1 per cent. respectively. The important features of fig. 3 seems to be (1) the steady fall of hæmoglobin in the control group and the sharp rise after delivery; (2) the break in the fall caused by the administration of iron to the experimental group; (3) the steady fall on discontinuing its administration, so that the curve runs parallel with that of the control group; and (4) the sharp rise after delivery. The total fall in hæmoglobin level in both the experimental and the control groups is statistically significant. The difference between the levels for the two groups is not statistically significant at any one particular stage of pregnancy, but the fact that after stopping iron the curves run parallel to one another suggests that at this time the average hæmogoblin level of the experimental group really did exceed that of the controls

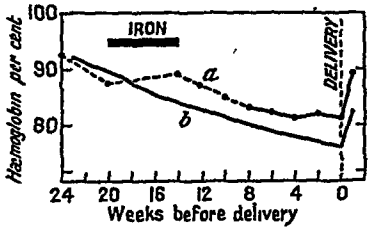

FIG 3—Average hæmoglobin curves for (*a*) experimental and (*b*) control groups of pregnant women. For meaning of interrupted line see text.

DISCUSSION

The administration of iron has been shown by others to check the fall of hæmoglobin during pregnancy (Corrigan and Strauss 1936, Toland 1936) There is therefore nothing original in this The fall after stopping the administration of iron is, however, a new observation and one which it is exceedingly difficult to explain. The following facts must be borne in mind. (1) the phenomenon is not peculiar to pregnancy, as was shown in the early part of this paper, (2) the administration of large (therapeutic) doses of iron for six weeks probably leads to the absorption of at least 500 mg. and possibly up to 5000 mg of the metal, which is certainly not excreted within the period of observation—if at all (Brock and Hunter 1937, Fowler and Barer 1937, Widdowson and McCance 1937), and these amounts, moreover, are outside fœtal requirements (Coons et al 1935, Bethell 1936), and (3) after the iron had been stopped, the experimental women's hæmoglobin level fell at the same rate as that of the controls. This requires confirmation, but it suggests that iron only stimulated the production of hæmoglobin while it was ...ually being administered The body, however, ... able to maintain the extra hæmoglobin in the circulation once it had been formed, but it was unable to prevent a fall in the concentration of hæmoglobin in spite of the greatly increased stores of iron. After the administration of iron had been stopped the level of hæmoglobin behaved as though iron had never been administered at all.

The following may serve as a tentative explanation of the observations One of the many factors regulating the level of hæmoglobin in the circulation is the amount of iron in the plasma; the more there is, the more active the marrow cells become When iron is not being administered, the amount of iron in the plasma is maintained at a low constant level by the high capacity of the storage organs. The administration of iron, however, temporarily raises the plasma iron, which stimulates the marrow to greater activity. It will be noted that this theory emphasises the amount of iron in the plasma rather than the amount in the body as the regulator of marrow activity. There is a totally different explanation, which seems improbable but is capable of direct verification—namely, that the administration of iron causes a decrease in the volume of circulating plasma.

The effects of stopping the administration of iron to women and children who have not been *proved* to be in a pathological state require rather serious consideration. The problem is as follows: does the raising of a person's hæmoglobin with massive doses of iron prove that the person was in need of iron—i.e., in a pathological state? It might very reasonably be held that, if the hæmoglobin fell to its original level when the iron was discontinued, no pathological state had been disclosed Against this view must be set the weight of clinical opinion, which has pronounced definitely in favour of raising the hæmoglobins of babies and pregnant women. No-one has dared as yet to make any definite pronouncement about "normal" women.

If it is impossible to achieve normal hæmoglobins in babies and pregnant women by physiological means —i e, without giving them therapeutic doses of iron—and if perfect health requires a normal hæmoglobin, clearly it is advisable to interfere with physiological processes in the best interests of the subject This obviously raises very fundamental questions about the sanctity of the normal which it would be out of place to discuss here

SUMMARY

(1) The administration of iron in therapeutic doses to pregnant women converted the fall in hæmoglobin, which was then in progress, into a rise.

(2) After the administration of iron had been discontinued, the hæmoglobin fell once more and at about the same rate as if iron had not been administered

Dr. R. A. McCance has been a very great help to me in the preparation of this paper. I am indebted to the Medical Research Council for a personal grant.

PROPHYLACTIC INOCULATION DURING THE INCUBATION PERIOD

By HARRY SCHUTZE, M B Melb , M D Würz
(*From the Bacteriological Department, Lister Institute, London*)

FROM time to time the opinion has been expressed that antityphoid inoculation undertaken during the course of a typhoid epidemic is dangerous It has been argued that, in consequence of an alleged negative phase resulting from the inoculation, some persons acquire the disease who would otherwise have only temporarily harboured the bacteria and so escaped infection, and others develop the disease in a more virulent form who would have experienced a milder attack No valid evidence in support of such argument is available Indeed the only adequately controlled observations, those of Ramsey (1935), demonstrated not only that typhoid infection in inoculated contacts was not provoked, but also that, certainly after the completed set of three doses and probably after even one or two, the incidence rate for the disease was lowered

In view of the lack of experimental work bearing on this question and in view of remarks on this subject in the medical press (*Lancet* 1937, *British Medical Journal* 1937 Ledingham 1937, Topley 1938) after the Croydon typhoid epidemic of 1937 it was decided to examine the effect on the death rate of inoculations given after infection, during what may be regarded as the incubation period

DETAILS OF EXPERIMENTS

The animal chosen was the mouse and the infecting organism *S typhi murium* A mortality of 50 per cent during an observation period of three weeks was aimed at among the controls, so that any effect the inoculations might have on the course of the disease would be indicated by either an increase or a decrease in the death rate In the ordinary white mouse as purchased by the Lister Institute, an infecting dose of between one and two thousand organisms of a 24 hour broth culture of the typhi murium strain employed, given subcutaneously between the shoulders achieved the desired result and was given to these animals consistently throughout the experiments The typhi murium vaccine was administered in four daily doses, subcutaneously in alternate flanks This system of multiple dosage was adopted with the idea of lowering the size of each individual inoculation Since the first deaths among the infected mice take place about the seventh or eighth day, inoculation was begun forty eight hours after infection, when the bacterium had well established itself, but there was still time to complete the vaccination before the animals began to die As a guide to what amount of vaccine could be tolerated and be effective, in the first experiment three groups of mice were given total doses of 1 5 million, 15 million, and 150 million of a heat killed vaccine, which, the body weights of man and mouse being compared, represented approximately 1, 10, and 100 equivalents of the amount of T A B vaccine administered prophylactically to a human being

The vaccine, it should be noted, was killed by heating to 53° C for 70 min and phenolised to 0 5 per cent after cooling On the following day 1 c cm was tested for sterility and after three days, being seen to be sterile, used in the experiment This was the only occasion on which a heat-killed vaccine so recently prepared was employed

The results of this experiment (table I) show clearly that, whereas the smallest vaccine dose is without effect, the two larger doses definitely are damaging to the animals, almost double the number of mice dying in each of these groups There was, however, one qualifying thought to be taken into consideration The vaccine given had produced local reactions in over half of the animals receiving the highest dose, some showed these subcutaneous infiltrations the day following the second dose of 20×10^8 organisms and others after the third dose of 40×10^8, no examination having been made after the last inoculation Since much larger doses of typhi murium vaccine had often been given in other experiments to mice without such reactions being noticed, it seemed possible that this particular batch of vaccine might somehow be responsible for the reactions An unusual feature of the batch was its recent manufacture only four days having elapsed since it had been heated and phenolised Its sterility had been proved by subculture of 1 c cm The possibility of an unusual toxicity, perhaps associated with its recent preparation remained

A second experiment was therefore planned in which a more mature vaccine was used it had been killed with chloroform at 37° C for 15 min six weeks previously Two groups of mice were given 0 10^8

TABLE I—FRESHLY KILLED VACCINE

Vaccine administered in 4 doses	Mice	After 21 days		A L E
		Dead	Percentage survivors	
1 5 × 10^8 organisms heat killed	24	10	58	14
15 × 10^8 organisms heat killed	24	17	29	11
150 × 10^8 organisms heat killed	24	17	29	15
Controls	24	9	62	17

A L E = Average length of life in days of those dying during the period of observation

and 600 × 10^6 organisms each in four doses as on the first occasion, but a further two groups were added which were given the same doses a fortnight before the infecting dose to establish contrastingly the ordinary prophylactic value of such doses. Special attention was paid to the development of subcutaneous reactions after vaccination; but, although the doses in the groups receiving the larger amount

TABLE II—VACCINE KILLED SIX WEEKS PREVIOUSLY

Vaccine administered in 4 doses	Mice	After 21 days: Dead	After 21 days: Percentage survivors	A.L.F.
6×10^6 organisms chloroform-killed before infection	24	5	79	17
600×10^6 organisms chloroform-killed before infection	24	1	96	19
6×10^6 organisms chloroform-killed in incubation period	24	5	79	15
600×10^6 organisms chloroform-killed in incubation period	24	13	43	15
Controls	24	12	50	14

varied from 40 × 10^6 on the first inoculation to 320 × 10^6 on the fourth, no sign of such inflammatory infiltrations as had been observed with the first vaccine was now noticed either in the mice inoculated prophylactically or in those receiving vaccine during the incubation period. One might infer from this that the unusual toxicity exhibited by the first heat-killed vaccine was not present in this second chloroform-killed vaccine. Table II summarises the results.

In this second experiment no detrimental effect of vaccination during the incubation period is to be noted. Even among the mice given the large amount of 600 million organisms, which represents, body-weight for body-weight, the equivalent of 400 human T.A.B. doses, no significant increase in mortality is observable, and the same dose prophylactically administered protected all but one for the period under observation, which indicates that the protective effect of the larger dose is not fully developed in the short time available when it is given during the incubation period, or that its immunising power is partly annulled by some detrimental effect. On the other hand, the smaller dose of 6 million organisms has more than halved the numbers dying among the controls. The same effect was produced by that dose given prophylactically.

In a suitable dose vaccination in the incubation period has protected and in no wise proved detrimental to the inoculated animals. It seemed increasingly likely that the poor results achieved in the first experiment were due to an unusual toxicity in the vaccine employed.

A further set of experiments was now devised to compare other vaccines killed in various fashions. (1) heat-killed and (2) chloroform-killed, as on the previous occasions; (3) heated at 60° C for two hours without subsequent phenolisation, and (4) chloroform-killed but given fresh on the day of manufacture. An exact repetition of the first 53°-killed vaccine was not attempted, for the exact day on which those organisms which survive this heating succumb to the phenol is not predictable, and the intention was to give as freshly prepared a vaccine as possible. In all other cases the vaccines were at least a month old.

In one experiment an antityphoid vaccine was included to consider its possible non-specific effect. Another experiment tested the influence of an enteritidis vaccine on the course of an enteritidis infection. Protection was not expected in this case, because, in my experience, with no vaccine, short of a living avirulent one, can mice be adequately immunised against infection with *S. enteritidis*, but, should vaccination in the incubation period exacerbate infection, this would be observable in an acceleration of the death-rate. The infective dose in this case consisted of 6000 organisms of a 24-hour 37° broth culture injected subcutaneously between the shoulders, four daily inoculations were given subcutaneously in alternate flanks, the first being given forty-eight hours after infection. In one typhi-murium experiment the custom of vaccinating with four daily doses was varied and the same amount of vaccine administered in two inoculations on the second and third days after infection. If possible, from an immunological point of view, this method of administration would obviously be preferable. The results of these experiments are given in tables III and IV.

From table IV one learns that enteritidis vaccine given as in the previous typhi-murium experiments has no influence on the course of the infection; in each group there are but 2 or 3 survivors after twenty-one days, and the average length of life is the same. There is no evidence of any provocative action.

Table III demonstrates once again—this time with three different preparations—that typhi-murium vaccine administered during the incubation period does not exacerbate the infection but on the contrary significantly lowers the mortality of the treated mice, that inoculation of the vaccine in two, instead of four, doses is an effective mode of administration; that non-specific treatment, as afforded by an antityphoid vaccine, does not influence the course of the disease;

TABLE III—VACCINES KILLED BY DIFFERENT METHODS

Vaccine administered	Mice	After 21 days: Dead	After 21 days: Percentage survivors	A.L.F.
6 × 10^6 organisms chloroform-killed, in 4 doses	24	6	75	12
6 × 10^6 organisms 60° C killed, in 4 doses	24	7	71	13
6 × 10^6 organisms 53° C killed, phenolised, in 4 doses	23	7	70	14
Controls	24	13	46	13
6 × 10^6 organisms 53° C killed, phenolised, in 2 doses	23	3	87	11
6 × 10^6 organisms chloroform-killed, fresh daily, in 4 doses	24	5	79	8
6 × 10^6 organisms, antityphoid vaccine, in 4 doses	24	7	71	13
Controls	23	7	69	13

TABLE IV—ENTERITIDIS VACCINE

Vaccine administered in 4 doses	Mice	After 21 days: Dead	After 21 days: Percentage survivors	A.L.F.
6 × 10^6 organisms, 53° C killed, phenolised	22	19	14	11
Controls	24	22	9	11

and that freshly prepared chloroform-killed vaccine is not damaging as was the freshly prepared heat-killed vaccine of the first experiment. There were no skin reactions as with the vaccine in the first experiment, but the dosage was considerably lower than that which produced them on the first occasion.

Since treatment with two doses in place of four appeared efficient this method was employed in the next experiment, which was undertaken to ascertain whether the rather arbitrarily chosen dose of 6 × 10^6 organisms was optimal. Batches inoculated with a

quarter of and with four times this amount were included The results are recorded in table V

TABLE V—EFFECTS OF VARIOUS DOSES IN A DIFFERENT STRAIN OF WHITE MICE

Vaccine administered in 2 doses	Mice	After 21 days		A L F
		Dead	Percentage survivors	
1·5 × 10⁸ organisms, 53° C killed phenolised	24	15	37	12
6 × 10⁸ organisms, 53° C killed phenolised	24	13	46	11
24 × 10⁸ organisms, 53° C killed phenolised	24	13	46	13
Controls	24	11	54	13

In this experiment, in contradistinction to those recorded in tables II and III, vaccination of mice in the incubation period has not increased their resistance, indeed, in one group, that receiving the smallest dose, a definite increase in mortality can be observed Since the mice employed on this occasion had been purchased from a different dealer and there was just a possibility of their possessing a diminished immunisability, animals from the original source were used with two batches of typhi murium vaccine in an attempt to repeat the results of the earlier experiments (table VI)

TABLE VI—EFFECTS OF VARIOUS DOSES IN THE ORIGINAL STRAIN OF WHITE MICE

Vaccine administered in 2 doses	Mice	After 21 days		A L F
		Dead	Percentage survivors	
6 × 10⁸ organisms, 53° C killed, phenolised	25	7	72	14
6 × 10⁸ organisms, 53° C killed, phenolised	23	5	78	12
Controls	26	6	77	13

The experiment recorded in table VI brings no evidence for provocation of the disease by inoculation, but there is also no evidence of immunisation It was noticeable, too, that the strain of *S typhi murium*

TABLE VII—RESULTS OBTAINED IN BLACK MICE

Vaccine administered to pure line E mice in 2 doses	Infecting dose	Mice	Dead after 21 days	A L F
6 × 10⁸ organisms 53 C killed phenolised	1600 org	14	14	9
Controls	1600 org	13	13	9
6 × 10⁸ organisms 53 C killed, phenolised	193 org	15	15	12
Controls	193 org	15	15	13

TABLE VIII—PURE LINE 1 MICE INFECTED WITH 150 ORGANISMS AND GIVEN 6 × 10⁸ ORGANISMS OF 53° C KILLED VACCINE

Vaccine administered	Mice	Deaths occurring on days after infection																Dead	A L F
		5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	21		
In 2 doses	40	0	1	0	4	6	6	4	0	3	1	2	0	0	1	0	1	40	13 1
In 4 doses	39	0	0	2	1	5	8	4	5	6	2	3	0	1	0	0	0	39	14 0
Controls	40	1	0	3	3	4	5	11	4	2	0	0	1	0	0	0	0	40	12 2

was just a possibility of their possessing a diminished immunisability, animals from the original source were used with two batches of typhi murium vaccine in an attempt to repeat the results of the earlier experiments (table VI)

The experiment recorded in table VI brings no evidence for provocation of the disease by inoculation, but there is also no evidence of immunisation It was noticeable, too, that the strain of *S typhi murium* was diminishing in virulence only 23 per cent of the controls now dying after the usual infective dose of between one and two thousand organisms

To study the effect of race on animal response and to work with a mouse strain more susceptible to infection with *S typhi murium*, the mice used in the next experiments were Little's C 57 blacks, a pure line labelled E in this laboratory and known from previous work (Schütze et al 1936) to be less resistant to salmonella infection So little resistance to *S typhi murium* have these mice that a mortality of 100 per cent is to be expected within three weeks, and a comparison of treated and untreated animals can rest only upon the rate at which they die In the first of these experiments the usual infective dose of between one and two thousand organisms was given, in the later ones 193 and 150 organisms were the amounts given, so that a more prolonged incubation period might ensue In the last experiment the effect of two doses of vaccine was compared with that of four doses, in all cases administration was begun as usual forty eight hours after infection The first two experiments are given in table VII, and the last in table VIII, where the daily death rate is recorded in addition

The results of these three experiments on pure-line mice confirm those already obtained on the ordinary white mouse Vaccination in the incubation period has no damaging effect The death rate is not more rapid among the inoculated than among the controls There is no suggestion that, whereas some favourably disposed individuals among the vaccinated have benefited from the treatment, as shown by a delayed death rate others less favourably disposed have fallen victims to the measure and succumbed more rapidly Mortality among the three groups proceeds at very similar rates

DISCUSSION OF RESULTS

An attempt to demonstrate whether prophylactic inoculation during the incubation period is harmful was carried out on mice with *S typhi murium* as the infecting agent and variously prepared vaccines prepared from the same strain for inoculation By comparing the death rate of treated and untreated animals it was hoped to estimate whether vaccination was damaging or not

In one experiment damage resulted from the treatment, and in this case the vaccine appeared to be at fault A four-day old specimen had been used and was found to give unusual local reactions an indication that the vaccine was abnormal The cause of this abnormality was not detected, whether in spite of the satisfactory sterility test the vaccine still contained living organisms, or whether because of its recent manufacture or for some other cause it was unusually toxic, remained undecided

In twelve other experiments, in which vaccine dosage varied from 1·5 × 10⁸ to 600 × 10⁸, only one gave a death rate notably below that of the control, 15 treated mice died within the three weeks of experiment as compared with 11 of the controls, there being 24 in each group, the dosage on this occasion consisted of the lowest tested, 1·5 × 10⁸ organisms Obviously such a result obtained from that number of animals is not significant A more reliable answer will be that given where a summary of results is taken

In the course of the various experiments on white mice 216 mice were treated with a vaccine dosage of 6 × 10⁸ organisms and had a survival rate of 72 per cent at the end of twenty one days, on the other hand only 59 per cent of the 120 untreated controls remained alive after the same period, a clear indication that not only does vaccination in the incubation period not do harm to mice infected with *S typhi murium* but also that it can noticeably afford them protection This dosage as given to the mouse

represented, body-weight for body-weight, the equivalent roughly of four times the amount of T.A.B. vaccine given to an adult human being. That the animals are not more definitely protected may well be due to the short time available for the process of immunisation. Vaccination took place on the second and third, sometimes as well on the fourth and fifth days after infection; the first death among the controls took place variously between the sixth and ninth days.

Similar tests were carried out with a pure line of mice particularly non-resistant to infection with *S. typhi-murium* and with the ordinary white mouse infected with *S. enteritidis* and treated with a corresponding vaccine. In both these cases, mortality being 100 per cent., comparison had to be made of the rate at which the animals died. The average length of life was in no way shortened by the process of inoculation. Vaccination during the incubation period was not damaging to the animals.

The conclusion, therefore, to be drawn from these experiments is that it should not be considered dangerous to inoculate a community during the course of a typhoid epidemic. If the source of infection is still undetected and possibly active, there would undoubtedly be time for prophylactic immunisation to intervene with beneficial effect. In those cases already infected with the bacterium no harm need be anticipated, and with the greater length of the incubation period in man more hope of prophylaxis may be entertained.

SUMMARY

(1) Mice were infected with *S. typhi-murium*, and two days later inoculation with a specific vaccine was begun.

(2) Such vaccination during the incubation period did not exacerbate the course of the disease.

(3) White mice (216) treated in this way showed a mortality of 28 per cent. at the end of three weeks, whereas untreated controls (120) had a mortality of 41 per cent.

(4) The average length of life of Little's C 57 black mice, a pure-line mouse particularly sensitive to infection with *S. typhi-murium*, was not decreased by vaccination in the incubation period.

(5) Vaccination with enteritidis vaccine after infection with *S. enteritidis* similarly did not accelerate the onset of the disease.

(6) The opinion is expressed that vaccination of a community during the course of a typhoid epidemic is by analogy to be recommended.

CLINICAL NOTES

CLOSTRIDIUM WELCHII SEPTICÆMIA AND PERITONITIS IN THE PUERPERIUM

RECOVERY AFTER M. & B. 693 AND SERUM

BY JOHN K. BAKER, M.R.C.S.

RESIDENT MEDICAL OFFICER, QUEEN CHARLOTTE'S MATERNITY HOSPITAL ISOLATION BLOCK, LONDON

Bliss and his collaborators (1939) have reported encouraging results of M. & B. 693 therapy in experimental *Clostridium welchii* infections in mice, but I have found no account of the employment of this drug in a severe human infection. Bohlman (1937) records success with sulphanilamide in surgical conditions and Sadusk and Manahan (1939) in two post-abortal septicæmias. In the following case the infection was unusually severe.

A woman aged 24, in her second pregnancy, was admitted to the Middlesex Hospital, London, on May 3 for medical induction of labour. It had been discovered by radiography that the uterus contained two fœtuses of about thirty weeks' gestation, and that the skull bones of one were overlapping; the other fœtus appeared radiologically to be anencephalic. At the end of her induction she expelled the first fœtus, which was anencephalic. At this point labour pains ceased, and it was thought advisable to await their return before attempting to deliver the second fœtus. Pitocin (3 units) was injected hourly, but after twelve hours pains had not returned. Examination then revealed the cervix about two fingers' dilated. Under anæsthesia it was dilated digitally, and the trunk and limbs of the grossly macerated second fœtus were delivered. The second head, however, remained in utero, and could only be delivered after perforation of the skull, and traction with the finger in the mouth. The placenta was expelled naturally.

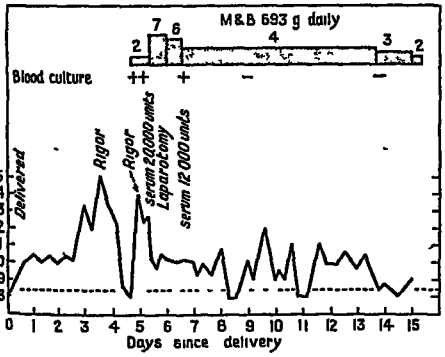
At the end of labour the temperature was 100·4° F., and twelve hours later, though the temperature was only 100° F., the lochia were noticed to be offensive, and she was transferred to Queen Charlotte's Hospital isolation block. She was then in good general condition. Forty-eight hours later she complained of lower abdominal pain, and began to pass greenish sloughs per vaginam. Later the same day she had a rigor and the temperature rose to 105° F. Glycerin was injected into the uterus and examination at this time showed induration of the parametrium on both sides. A second rigor occurred twenty-four hours after the first, and blood taken at this time yielded *Cl. welchii* on culture. Next morning—i.e., the sixth day after delivery—she developed signs of general peritonitis, with much distension. Concentrated anti-gas-gangrene serum (20,000 units) was given intravenously diluted with saline, and during the course of the day M. & B. 693 7 grammes by mouth. The abdomen was opened by Mr. L. C. Rivett in the evening under gas-and-oxygen anæsthesia, by which time her condition had become desperate.

On opening the peritoneal cavity there was an almost explosive escape of gas, and about 10 *oz.* of bloodstained serous effusion was found in the general cavity, the pouch of Douglas containing thick pus. Cultures from fluid taken at the time of laparotomy grew *Cl. welchii* and anaerobic streptococci, not only from the general peritoneal cavity but also from the thick pus. No attempt at hysterectomy or thorough exploration of the abdomen was made, the surgical measures being limited to drainage, through the incision, of the pouch of Douglas and the general peritoneal cavity.

At the end of the operation and for the next six hours the patient appeared to be moribund, with a bluish colour, shallow rapid respiration, and an uncountable pulse; but at the end of that time she recovered sufficiently to take more M. & B. 693 by mouth. For two days after this her condition appeared most precarious, and as she seemed profoundly toxic another 12,000 units of serum was given by the same technique on the second postoperative day. It seems probable however that the toxic appearance was due more to the M. & B. 693 than to the infection, although at this time the blood-culture was still positive for *Cl. welchii*. For a week after the opera-

tion the lochia consisted of greenish pus and sloughs of uterine muscle

The subsequent progress may be estimated from the accompanying chart The total of M & B 693 was 44 g in nine days Convalescence was interrupted by a severe urinary infection with *Streptococcus fæcalis*, and the formation of an inflammatory mass in the pelvis late in convalescence, both of which responded well to medical treatment At the time of her discharge, fifty-four days after admission, the uterus was surprisingly mobile and of normal size



Temperature and treatment chart
+ = positive blood-culture
− = negative blood culture

Wrigley (1930) postulates certain conditions attending labour likely to be followed by gas forming infections—viz, (*a*) the fœtus is dead for some hours in utero, (*b*) the organism must be introduced from outside the birth canal by manipulations, and (*c*) the manipulations must to some extent damage the maternal tissues in order to afford a portal of entry for the organism All these conditions were fulfilled in the case described

This puerperal case did not present any of the signs of hæmolysis so often noted in postabortal *Cl welchii* septicæmias, such as hæmoglobinuria and pigmentation of skin (Hill 1936)

During the twelve hours preceding operation and in the course of the next nine days this patient received 44 g of M & B 693 by mouth It would be unwarrantable to attribute any specific action to the drug on the evidence of this case alone, especially as specific serum was administered at the same time, but the ultimate recovery from so grave an infection is very encouraging, and in view of the accumulating experimental evidence (Bliss et al 1939, Sadusk and Manahan 1939, Buttle 1939) it seems that further trial of the drug in *Cl welchii* infections is justified

The total dose of serum in this case was only 32,000 units In two non fatal postpartum septicæmias reported by Hill (1936) and three postabortal cases reported by Buchanan (1932) the average dose was 243,600 units Many patients have received much larger quantities and failed to survive

I am indebted to Mr L C Rivett and the honorary staff of Queen Charlotte's Hospital for permission to report this case, and to Dr E D Hoare for the bacteriological reports and to Mr O Lloyd and Dr T G Williams of the Middlesex Hospital for the obstetric story I should like to express my gratitude to Dr Leonard Colebrook for his invaluable help in the preparation of this report

FATAL AGRANULOCYTOSIS FOLLOWING TREATMENT WITH M. & B. 693

By HAMISH NICOL, F R C S E
CONSULTANT IN VENEREAL DISEASES AT ST STEPHEN'S (L C C) HOSPITAL, LONDON AND
BERNARD FREEDMAN, M B Lond, M R C P
ASSISTANT MEDICAL OFFICER AT THE HOSPITAL

AGRANULOCYTOSIS is a well known complication of sulphanilamide therapy, but only 5 cases have hitherto been reported following the use of M & B 693 (Barnett et al 1939, Coxon and Forbes 1938, Johnston 1938, Sutherland 1939, Tzanck et al 1939) In none of these was an autopsy described

Our patient, aged 60, a hawker by trade, was admitted to St Stephen's Hospital on May 1, 1939, with gonococcal urethral discharge for a week and a right-sided epididymo-orchitis Apart from this (and pediculosis) he was healthy The blood gonococcal complement-fixation test was positive, the blood Wassermann reaction negative and the blood Kahn "suspicious"

Two days after admission M & B 693 therapy was started, he was given 4 g a day for five days, then 3 g a day for a further sixteen days making 68 g in twenty one days He was also given potassium citrate 20 grains t d s, fomentations to the scrotum till the fourteenth day, and Iodex applications till the twenty-first day

After seven days of treatment there was no urethral discharge, the epididymitis was subsiding, and the patient appeared in good general health All treatment was stopped on the twenty-first day, the temperature, pulse- and respiration rate having been normal throughout But six days later—i e, twenty-seven days after beginning treatment—the patient felt unwell He complained only of malaise and frontal headache, he did not complain of his throat In the morning his temperature rose to 103° F There were no abnormal signs save a slight redness and "fleshiness" of the fauces That evening the temperature was 105° Hæmolytic streptococci were grown from a throat-swab taken at this stage

Next morning the patient was very ill and drowsy The face was flushed, the tongue was dry with a central brown coat, and there was white exudate on the right tonsil The total white cell count was 300 cells per c mm, all cells seen being lymphocytes Hæmoglobin, 72 per cent, red cells, 4,360,000, colour-index, 0 83, punctate basophilia present Urine porphyrins, not detected, urobilin, present ++, urocythrin, present + He was given Pentnucleotide 10 c cm four times and Hepastab 1 c cm twice, on the day agranulocytosis was diagnosed In the evening his condition was worse and the right tonsil was brown and becoming gangrenous He died the next morning, forty-eight hours after the onset of symptoms, and eight days after the M & B 693 had been stopped

Post-mortem findings—Sloughing of fauces and pharynx Right sided epididymitis Toxic softening of heart muscle Lungs deeply congested, but otherwise normal Toxic changes in liver and kidneys

Histology—Lymph-gland post-mortem degeneration, no leucocytes seen, anthracosis Spleen post-mortem degeneration, no leucocytes seen. Bone-

marrow (sternum): no leucopoiesis; mild active erythropoiesis.

There are several peculiar features in this case Firstly, there was a clear interval of six days' good health between the cessation of treatment and the onset of symptoms of agranulocytosis. Barnett et al (1939) described a fatal case of appendix abscess from which pneumococci were cultured, in which the white count did not fall till three days after cessation of M & B. 693 administration, though this patient, unlike ours, had not yet been cured of the original condition Death in Barnett's case was due to hæmorrhage from neck abscesses, and cannot be said to have been directly due to agranulocytosis In the other 4 recorded cases agranulocytosis appeared during, not after, the administration

Secondly, hæmolytic streptococci were grown from a throat-swab Did these bear any causal relationship to the agranulocytosis? Clinically the appearance of the throat was that of the gangrenous pharyngitis of agranulocytosis. In the 5 previous case-reports throat-swabs are not mentioned

Thirdly, there was gross reduction of the lymphocytes (300 per c mm.) and complete disappearance of the granular cells This indicates a depression of all the leucopoietic tissues, and the microscopical appearances of spleen, lymph-gland and bone-marrow correspond The patient died before a platelet-count was performed but, as far as could be determined from the ordinary stained film, their numbers were approximately normal The state of the leucopoietic tissues was not reported on in the 5 cases already referred to. In those of Coxon and Forbes and Barnett et al there was gross reduction of all types of white cells, the total counts being 100 and 75 respectively In Johnston's, Tzanck's and Sutherland's cases, however, the lymphocyte count was within normal limits, the figures being 2200, 1000 and 1500 respectively, with polymorphs at zero

Our patient received 68 g. of M & B 693 in twenty-one days This is comparable to the dosages in the other cases—namely:

Sutherland	52 g. in eighteen days	Streptococcal puerperal sepsis
Coxon and Forbes	54 g. in seventeen days	Typhoid
Barnett et al	80·9 g. in twenty-six days	Appendix abscess
Johnston	54 g. in eleven days	Streptococcal endocarditis
Tzanck et al	18 g. in fifteen days	Lobar pneumonia

We wish to thank Sir Frederick Menzies, medical officer of health for the county of London, and Dr. D. S Sandiland, medical superintendent of St. Stephen's Hospital, for permission to publish the clinical details of this case; Mr. Neville Stafford, H M coroner for West London, and Dr. Keith Simpson for permission to publish the post-mortem report, and Dr. G. W. Goodhart, pathologist to the L.C.C. Group Laboratory, for preparing and reporting on the sections.

SECTION OF OBSTETRICS AND GYNÆCOLOGY

THIS section, under the presidency of Prof. R. W. JOHNSTONE (Edinburgh), discussed

Postpartum Hæmorrhage

Dr. ROBERT M CORBET (Dublin) said that in Dublin the third stage of labour is treated in the most conservative manner possible In about two-thirds of the normal cases the fundus is not touched after delivery until the signs of placental separation are present; in the remaining third the fundus is controlled manually, but no massage is allowed After an operative delivery the fundus is usually controlled. Injection of the umbilical cord with saline is practised when the placenta is retained, and expression without anæsthesia has failed It appears to be successful in about a third of the cases, but should not be relied upon in the presence of hæmorrhage In 28,749 deliveries in three years there were only 147 cases (0·5 per cent.) in which manual removal of the placenta was required

Postpartum hæmorrhage Dr. Corbet divided into three distinct types. (1) placental site hæmorrhage, due to premature separation of the placental margin, (2) true atonic hæmorrhage, where there is no bleeding till after delivery of the placenta, and (3) traumatic hæmorrhage, where the bleeding comes from lacerations in some part of the birth canal The cause of partial separation is usually ill-advised handling of the uterus and premature attempts to express the placenta or else, after prolonged operative delivery, a combination of the effects of the anæsthetic and mechanical interference with the placenta. Morbid adhesion of the placenta is rare The onset of bleeding due to partial separation was seldom sudden and severe. A little bleeding was noticed at the vulva; the fundus was found to be above the level of the umbilicus, the placenta was thought to be separated and attempts at expression were made A quantity of clot was expressed but the placenta was still retained. The bleeding appeared to stop, and further time was given for separation, the whole process might be repeated, perhaps several times One of the traps of postpartum hæmorrhage was that bleeding, without injury, might not produce any alteration in the patient's appearance or pulse until much blood had been lost. Up to a point, the loss was compensated for by vasomotor control, but when the limit of compensation had been passed, the patient's collapse might be sudden and profound.

Treatment was complicated by the retention of the placenta Before starting active measures for its removal, the patient's general condition had to be considered carefully. If necessary, efforts should be directed to restoring her by means of intravenous or submammary saline, transfusion, warmth, morphia, raising the foot of the bed, and perhaps bandaging the limbs. No attempt should be made to remove the placenta until the patient's general condition had improved. Manual removal in collapsed patients was a very dangerous operation It was essential to have a complete plan of action in one's mind and to be able to go from step to step, with speed and confidence Dr Corbett advised the following. (1) pass a catheter, (2) rub up the uterus and attempt to express the placenta by the Dublin method, (3) attempt to express it by Credé's method. (4) give an anæsthetic and repeat Credé's method, (5) remove the placenta manually, stop the anæsthetic, and give oxytocic drugs, (6) employ bimanual massage,

(7) give a hot intra uterine douche and (8) pack the uterus The best material for packing was iodoform gauze, 6 in wide, and long enough to pack the uterus with one piece The pack should not be allowed to remain in for more than 24 hours and might often be removed after 8 hours unless the hæmorrhage was of traumatic origin

Oxytocic drugs given before the uterus was empty might produce irregular contraction and make the subsequent removal of the placenta more difficult They should therefore not be used until exploration of the uterus has proved the absence of any hour-glass contraction Pituitary extract (10 units) and ergometrine (0 5 mg) might then be given intramuscularly The ergometrine could be repeated if required as it was free from the undesirable side effects sometimes associated with pituitary extract In carrying out the suggested plan of action, speed was essential, and valuable time was often wasted in arriving at a decision to remove the placenta manually and to pack the uterus

In true atonic hæmorrhage the bleeding started a variable time after delivery of the placenta, and there was no bleeding in the third stage itself Although this type of hæmorrhage might occur after perfectly normal labours, it was more common after difficult deliveries with prolonged anæsthesia In treating it, oxytocic drugs should be given at once Many cases required nothing more than this and abdominal massage of the uterus But if the bleeding continued, the treatment was the same as in the first type of hæmorrhage discussed

In traumatic hæmorrhage the bleeding might come from lacerations in any part of the genital tract, the worst being those of the cervix, these might involve the vaginal vault or even the lower uterine segment In most cases, the diagnosis was made when bleeding continued in spite of the uterus being firmly contracted Where the laceration could be exposed in its entirety stitching would control the hæmorrhage, if this was not possible, as when the laceration extended into the vaginal vault or the lower uterine segment, the laceration, the uterus and the vagina should be packed after removal of the placenta

Investigations into the causes of maternal mortality showed that postpartum hæmorrhage was responsible for 7 5 per cent of the deaths in New York, 6 3 per cent in England and Wales, and 3 9 per cent in Scotland If this mortality was to be reduced the following points must be remembered Anæmia must be treated during the antenatal period Interference with the normal uterine action during the third stage must be avoided The danger of attempting delivery through the partially dilated cervix must be realised Failure of the normal mechanism of placental separation must be detected as early as possible Adequate equipment must be prepared to deal with the hæmorrhage rapidly particularly where the patient's history suggests the likelihood of bleeding An ounce of forethought may save pints of blood

Prof JAMES HENDRY (Glasgow) divided cases of postpartum hæmorrhage into three grades according to the blood lost In grade 1 the loss was a little greater than normal In grade 2 compression of the uterus was necessary to control hæmorrhage In grade 3 blood transfusion and drastic measures were needed

First and second pregnancies and pregnancies from the seventh onwards had a greater tendency to fall into grade 1 Parity had no influence in producing grade 3 A long labour completed spontaneously did not predispose to postpartum hæmorrhage On the other hand, where labour did not terminate normally and general anæsthesia was necessary, there was a greater predisposition Gas and air analgesia did not increase the incidence, whereas morphia did Spinal anæsthesia reduced blood loss quite definitely, compared with delivery under general anæsthesia It was of great value to pull the uterus up out of the pelvis and massage it through the abdominal wall rather than push it downwards Blood transfusion had reduced the mortality in postpartum hæmorrhage by 20 per cent In the prevention of postpartum hæmorrhage it was important to conserve the patient's strength during labour with glucose and sedatives In normal cases the uterus should not be touched during the third stage until the placenta had separated

Dr ÆNEAS MACKENZIE (Tain) said that during 33 years of rural general practice, he had conducted 1301 deliveries Of these 32 had suffered from postpartum hæmorrhage He considered the causes were exhaustion of the patient, shock and fall of blood-pressure, resulting in failure of the uterine musculature to retract The exhaustion and shock might be due to prolonged labour, too rapid labour, or over distended uterus The danger of postpartum hæmorrhage after the birth of an unusually large child could in part be avoided by inducing labour if a woman had gone past term He had had no deaths from postpartum hæmorrhage

Prof FARQUHAR MURRAY (Newcastle) suggested that some of the rare and unaccountable hæmorrhages from an apparently normal empty uterus might be due to unusually large arterial trunks close to the placental site He had never seen sepsis after a manual removal followed by an intra uterine antiseptic douche, if this had been done while the patient was in fairly good condition Delay, from a fear of causing sepsis or because the blood-loss was intermittent and slight, was responsible for many bad results He was against packing the uterus, many cases at present treated by blood transfusion would, he thought, do equally well on gum or glucose saline

Dame LOUISE MCILROY (London) thought manual removal was very dangerous because of the high sepsis rate afterwards She did not think that morphine predisposed to postpartum hæmorrhage She advised the injection of hot glycerin into the uterus as a hæmostatic Miss BEATRICE TURNER (London) also spoke in support of hot glycerin as a useful hæmostatic

Sir BECKWITH WHITEHOUSE (Birmingham) paid a tribute to the care with which obstetrics was conducted in Scotland This was shown in the lower mortality figures for postpartum hæmorrhage as compared with England He advised injection of pituitary extract during the third stage should hæmorrhage occur from a partially separated placenta He was against manual removal in the absence of postpartum hæmorrhage or in cases in which the hæmorrhage could be controlled effectively by other means

Prof DUGALD BAIRD (Aberdeen) said that the use of spinal anæsthesia for forceps delivery greatly reduced the incidence of postpartum hæmorrhage He deplored the use of intra uterine douches and stressed the importance of treating secondary anæmia during pregnancy as a means of preventing serious postpartum hæmorrhage The incidence of manual removal of the placenta in 1000 deliveries in the Aberdeen Maternity Hospital during 1938 was 0 6 per cent

Prof J B DAWSON (Dunedin) did not approve of the routine use of oxytocic drugs after normal delivery He agreed with Professor Hendry that morphine

predisposed to postpartum hæmorrhage He did not fear manual removal as much as some of the other speakers

Sir EWEN MACLEAN (Cardiff) liked gas-and-air analgesia in midwifery and did not think it predisposed to postpartum hæmorrhage He was in favour of midwives being allowed to give this analgesia.

Dr H. R FREDFRICK (Port Talbot) said it was consoling to find that the general practitioner was not always to blame for the bad results which were at times attributed to him.

Professor JOHNSTONE (Edinburgh) commented on the divergence of opinions expressed He did not think one could do harm by placing the hand gently on the fundus before the placenta was delivered.

Dr CORBET, in reply, said he sympathised with the general practitioner in his obstetric difficulties. He agreed about the importance of treating anæmia in the antenatal clinic He re-emphasised the need for conservatism in the third stage of labour and deprecated unnecessary massaging of the uterus before the delivery of the placenta

SECTION OF PHARMACOLOGY, THERAPEUTICS AND ANÆSTHETICS

AT a meeting of this section Dr J ROSS MACKENZIE (Aberdeen) took the chair after Prof DAVID CAMPBELL, the president, had opened the proceedings.

Anæsthesia in Dental Surgery

Dr. FREDA B. PRATT (Oxford), in a paper dealing with the significance of cyanosis in nitrous-oxide anæsthesia, pointed out that anæsthesia in dental surgery is usually performed upon normal healthy unpremedicated patients In such subjects cyanosis denotes a reduction of oxygenation of the blood below normal. With anæsthetics other than nitrous oxide cyanosis signifies respiratory obstruction. With such a weak anæsthetic as nitrous oxide, it is necessary to utilise anoxia to reinforce the effect, and therefore in many patients, particularly if unpremedicated, cyanosis is unavoidable. Cyanosis is not of itself a sign of danger, nor its absence an assurance of safety It does not occur until 5 g. of the hæmoglobin in the arterial blood is in the reduced form. The average patient has 15 g of hæmoglobin per 100 c.cm. of blood, and will become cyanosed if he inhales a mixture containing approximately 10 per cent. of oxygen, since this is capable of oxygenating only two-thirds of the available hæmoglobin A patient with less than this amount of hæmoglobin would not become cyanosed on the same mixture, but a patient with more would become more markedly cyanosed. Patients can be divided into plethoric, normal and anæmic types, and slides were shown to illustrate the fact that when inhaling a mixture of nitrous oxide with say 10 per cent. oxygen the plethoric patient becomes cyanosed earliest, and that a patient with severe anæmia can never become cyanosed, although he is much more depressed than the plethoric or normal patient. The danger of relying on cyanosis as a guide to the depth of anæsthesia is therefore evident The inevitability of marked cyanosis in the plethoric patient with nitrous oxide alone was discussed. The fact that the automaticity of respiration is the cardinal sign of anæsthesia with nitrous oxide was stressed. Various methods of subduing the anæsthetic-resistant patient were reviewed.

Dr. JOHN GILLIES (Edinburgh) described the use of cyclopropane in dental surgery He had found that the greater potency of this agent over nitrous oxide made it possible to deal easily with the unpremedicated, robust adult. After a face-mask induction of anæsthesia, the patient usually remains unconscious long enough to enable completion of the type of dental work undertaken on the ambulant subject If necessary, anæsthesia is prolonged by nitrous oxide, administered nasally. Recovery is rapid and uneventful In the unpremedicated patient, the secretions are stimulated by cyclopropane but not to an inconvenient degree, and the incidence of vomiting is higher than after nitrous oxide alone All the cases undertaken had proved very successful.

Dr W. S MCCONNELL (London) spoke on the use of Evipan in dental surgery on ambulant patients The evipan is injected when the patient is upright in the dental chair The semi-reclining position is not favoured because saliva gravitates backwards, and irritates the pharyngeal wall initiating a cough. The patient is prevented from slipping by supporting him round the pelvis with a strap A prop should be inserted before anæsthesia is begun, and the dentist should hold up the lower jaw to prevent the prop slipping in case the patient yawns. The whole of the estimated dose is injected rapidly. The nosepiece is then placed in position, and anæsthesia continued with nitrous oxide. The dose of evipan administered varies from 0·25–1·0 g The method is especially useful for the vigorous adult and for patients who dislike induction by inhalation methods The patient can leave the dental surgery from ½ to 1½ hr after the operation Chronic alcoholic patients eliminate the evipan rapidly. Pentothal is not favoured because of the marked respiratory depression following its use

Dr. A. H MACKLIN (Dundee) said that he had long held and taught that cyanosis is not of itself harmful but is an inevitable part of nitrous-oxide anæsthesia in the average patient. He stressed the fact that the anæmic patient can be seriously depressed from nitrous oxide, though failing to show cyanosis In his opinion the basis of all forms of anæsthesia is asphyxia, which in the case of nitrous oxide is due to the exclusion of oxygen from the inhaled gases, and with other anæsthetics, due to the poisoning of the cells by anæsthetic which prevents their using the circulating oxygen. Regarding the general technique of dental anæsthesia, he insisted on the necessity for a tight gauze pack in the pharynx and therefore considered the administration of nitrous oxide by a nasal inhaler to be contra-indicated. He advocated the use of a pharyngeal tube.

Dr. B E. COOK (Doncaster) stated that she used ethylene as a routine for dental work. The resulting anæsthesia, deeper than is possible with nitrous oxide, proved useful in the robust adult. It was particularly useful for children. Recovery was uneventful. She employed ethylene without any mishap in rooms where a naked flame was present.

Dr R J. CLAUSEN (London) stated he had found the operating conditions afforded by ethylene to be excellent for dental surgery, but after being anæsthetised by ethylene experimentally, he was impressed by the prolonged postanæsthetic depression, a factor which lowered his opinion of the usefulness of this agent in the ambulant patient

Dr H. W. FEATHERSTONE (Birmingham) described his personal experience of prolonged postanæsthetic depression following cyclopropane

Dr. A. BARNSLEY (Guildford) described a simple method for facilitating venepuncture.

Dr. R E. MANSFIELD (London) asked if Dr. Pratt considered secondary saturation a justifiable procedure

in dental work in cases where an adjuvant to nitrous oxide alone would ordinarily be necessary She mentioned the suitability of vinesthene for dental work in children

Dr J H T CHALLIS (London) spoke of the difficulties of dental anæsthesia in children, and of the lack of any really ideal method

Dr PRATT, in reply, said she considered the use of ethylene in the presence of a naked flame to be very dangerous In her opinion there were degrees of "secondary saturation' Full saturation was dangerous for patients with failing circulation and in any case was not justified for dental extractions There were resistant patients who could be subdued by a modified saturation—i e , by anæsthetising them deeply with nitrous oxide for a short time and then lightening anæsthesia before extractions were commenced For the very resistant patient she preferred to supplement light nitrous oxide anæsthesia with evipan or ethyl chloride

Anæsthesia in Genito-urinary Surgery

Dr T A B HARRIS (London) said that in genito-urinary work anæsthesia may be required to allow either diagnostic investigation or surgical operation Cystoscopy in women can always be performed without an anæsthetic In men, local, general or spinal anæsthesia can be employed The disadvantage of general anæsthesia is its effect of diminishing urinary secretion, but evipan or avertin followed by nitrous oxide delays the secretion of indigo carmine for 1–2 minutes only At St Peter's Hospital for Stone, low spinal anæsthesia is favoured for this procedure If it is known that the cystoscopy will take only a short time, a satisfactory anæsthetic is Omnopon and scopolamine, followed by evipan Pentothal is believed to produce powerful contractions of the bladder, and is therefore contra indicated For cases where anæsthesia is required for surgical intervention, if the patient's general condition is very poor local anæsthesia should be employed An analysis of 24 deaths in poor-risk cases whose average age was 69, and who were dyspnœic at rest, revealed that the most important single factor increasing any risk is cardiac decompensation In this connexion, a too high spinal anæsthetic is dangerous because the stagnation of the circulation in the area anæsthetised provides an increase in the peripheral resistance and therefore increased strain on the heart For this reason in renal surgery unilateral spinal anæsthesia is preferred to bilateral Either avertin or evipan basal anæsthesia followed by general anæsthesia are satisfactory The avertin should be washed out of the rectum just before general anæsthesia is begun, in order that it should not delay the postoperative recovery During convalescence, massage and re educational breathing exercises are important in preventing postoperative complications

Dr CLAUSEN stated that he uses opoidone scopolamine as premedication for cases proceeding to general anæsthesia He dislikes heavy basal anæsthesia, and does not use avertin Drimyl ether has many advantages for general anæsthesia Ethylene-oxygen is very satisfactory for prostatectomy

Dr MCCONNELL considered the all important factor in this type of surgery to be the avoidance of anoxæmia Evipan followed by gas, oxygen and vinesthene delivered from a drip bottle is very satisfactory for prostatectomy If required ether can be given in addition to the vinesthene

Dr P M OVERTON (Bolton) stated that he had found epidural anæsthesia extremely satisfactory both for genito urinary and general abdominal surgery

Dr H H PINKERTON (Glasgow) favoured the use of cyclopropane in the poor-risk patient on account of its freedom from toxicity

Dr FEATHERSTONE was of opinion that a healthy patient could be subjected to any type of anæsthesia with satisfactory results, but that for the poor-risk patient the question of choice of anæsthetic might be very important

Dr HARRIS, in reply, said he considered the use of epidural anæsthesia to be unjustified It was a method fraught with danger from the risk of injecting a heavy dose of procaine directly into the spinal canal, and had been superseded by intrathecal anæsthesia He thought vinesthene a very suitable anæsthetic for the "chesty" elderly patient Cardiac arrhythmia was a frequent complication of cyclopropane anæsthesia which on this account should not be regarded as non toxic

Advantages and Disadvantages of Intratracheal Anæsthesia

An occasional paper on this subject by Dr ROSALIND P MILNE and Dr ROSS MACKENZIE, both of Aberdeen, was read by the former The advantages of intratracheal anæsthesia and the conditions for which it was particularly suitable were reviewed After operations for the repair of cleft palate she recommends that the tube should be left in situ for 12–24 hours—i e , the period during which acute œdema of the glottis might occur She considers that passage of a tube through the nose by the blind method might, if there was coughing and spasm occurred, cause damage to structures in the region of the larynx In her opinion blind intubation should be reserved only for the rare cases in which use of the laryngoscope is contra-indicated Even for oral surgery, oral intubation is favoured

Dr CHALLIS found blind intubation very satisfactory and safe The possibility of causing damage with a laryngoscope must always be borne in mind

Dr GILLIES pointed out that the tube employed should be large enough to provide an adequate airway If the tube were too small to allow free expansion of the lungs pulmonary complications might result

Dr ROSS MACKENZIE replied that blind intubation should be reserved for the expert The novice is not able to avoid the dangers inherent in this method and can be certain of passing the tube successfully only if a laryngoscope is used

---

SECTION OF DISEASES OF CHILDREN

WITH Mr GORDON BRUCE (Aberdeen) in the chair, this section discussed

Genito-urinary Infection in Childhood

Dr WILFRID SHELDON (London) said that the work of Chown, and Wilson and Schloss showed that such infections were often blood born, producing an interstitial suppurative nephritis rather than a pure pyelitis Pyelonephritis was the more correct term and pyelitis seemed to be a misnomer The essential point in diagnosing urinary infection was the finding of pus in the urine What number of pus cells should be regarded as of pathological significance? Cunnings and Alice Dickie had shown that urine from healthy boys usually contained no pus The latter investigated the urine of 900 children free from urinary infection and found that using a high power lens 50 per cent of healthy girls had pus cells up to two per field Ordinary specimens of urine were used

after the vulvæ had been swabbed, a drop being taken from a shaken-up specimen

Pyelonephritis was most common in infancy. Craig reported 61 instances in the neonatal period, while in Graham's series of 435 cases, more than half occurred during the first year. The sex-incidence was important There was a preponderance of female cases but this applied to the period after infancy. During the first two years, boys were affected almost as frequently as girls, while in the new-born there was actually a preponderance of boys over girls The high incidence of urinary infection in infancy had been ascribed to ascending infection through contact between soiled napkins and the vulvæ, but this argument was not valid since at this age there was no sex preponderance in girls. The probable cause was the commonness of gastro-enteritis at this time of life There was often a history of bowel upset immediately before the onset of pyelonephritis The infection was presumably blood-born and rigors at the onset indicated a septicæmic state.

The symptomatology of neonatal infection often differed from that in older children The onset might be vague, with restlessness, vomiting, diarrhœa, pallor, collapse and pyrexia. The diagnosis of dehydration fever of the new-born should only be made after urinary infection had been excluded Dehydration fever was relieved quickly by fluids, but the diuresis thus produced might equally well alleviate a urinary infection. Collapse attacks were alarming. In an infant a few days old, they should always suggest urinary infection Vomiting was important, especially in more chronic cases When an infant vomited repeatedly, passed unhealthy motions and failed to gain weight, urinary infection should always be thought of.

Breast-fed babies were almost exempt from pyelonephritis, and less prone to gastro-enteritis, scurvy and rickets. So vitamin deficiency might be a factor.

TREATMENT

In acute pyelonephritis alkalis were the remedy of choice. They sometimes caused slight diarrhœa in young children, but this was lessened if citrates and bicarbonates were used instead of citrates alone Mandelic acid was an acid preparation and, for an acutely ill child with a high temperature, treatment with alkalis was on general grounds to be preferred. Alkalis would clear up cases only if uncomplicated by urinary-tract deformity On the other hand, mandelic acid and sulphanilamide were likely to sterilise the urine even in the face of such deformity, hence one might be lulled into a false sense of security. If alkalis were used, full urinary investigation need only be carried out if there was no response to treatment It was sometimes difficult to get the urine alkaline and it was essential to give alkalis by night as well as by day

Chronic pyelitis called always for exclusion of congenital deformity. Full investigation should include culture of the urine, intravenous pyelography, cystoscopy and ascending pyelography. The latter was possible from birth in a female infant and in boys after the age of three years. Unilateral infection might be dealt with surgically. Alkalis, hexamine, vaccines and sera were generally without effect in chronic cases. Mandelic acid was effective with *Bacillus coli* and *Streptococcus fæcalis* but was of little use with staphylococci and *Bacillus proteus* A concentration of 0·5–1·0 per cent. must be obtained and the pH of the urine must be at least 5·5 At the age of a year, 3 grammes of mandelic acid every 24 hours should be given An extra acidifying agent was usually necessary, such as ammonium phosphate (15 to 60 grains according to the age of the patient and the methyl-red reaction of the urine) The sulphanilamide group were of definite value in chronic urinary infections They were not effective against *Str. fæcalis* but would give prompt success in *B. coli* infections and would clear up that most resistant organism *B. proteus* Sulphanilamide worked best in a slightly alkaline urine and should therefore be given with a small dose of alkali Even in the face of renal damage, one was able to get a sufficient concentration in the urine The dose of sulphanilamide varied with the age For a baby half a tablet might be given 6 hourly. The dose at one year was half a tablet 4 hourly, while for older children it was one tablet every 4 hours. All the various preparations seemed to be equally effective

SURGICAL TREATMENT

Mr. MATTHEW WHITE (Glasgow) said that organic lesions should, if possible, be dealt with surgically. In young children this was no easy task, and for this reason the high incidence of organic lesions had been overlooked in the past In the literature figures as high as 40 per cent were given. He had studied 125 chronic cases admitted for urinary investigation and 150 medical cases from the wards of Professor Fleming. The difference in age in the two series was striking In the medical series the majority were under the age of two years, while many were under one. There were no cases in the surgical group under one year, the majority being over five. Medical cases were investigated chiefly by intravenous pyelography, but in surgical cases cystoscopy, catheterisation of ureters, and retrograde pyelograms were done

The organic lesions found were hydronephrosis with or without obstruction, congenital deformities and renal calculi In the medical series of 150 children, only two-thirds were subjected to intravenous pyelography, the others recovering so quickly that they were discharged Organic lesions were found in 30 per cent In the surgical series of 125 children, 65 had pyuria Of these 27 or 41 per cent showed organic lesions The high incidence in boys (73 per cent.) was partly because stone was more common in male children In the whole series, 18 cases had renal calculi but pyuria was present in only 8

The commonest organic lesion was hydronephrosis It varied from slight enlargement of one pelvis to gross dilatation of both sides The origin was still obscure but two definite types could be recognised, one due to mechanical obstruction, usually congenital stenosis in some part of the urinary tract, and one without any obvious mechanical block. In the latter type, cystoscopy showed a large and patent ureteric opening. The hydronephrosis might be unilateral or bilateral The origin was as yet obscure but some cases had in addition Hirschsprung's disease There might be a neuromuscular disturbance responsible for both lesions. Satisfactory radiograms of the urinary tract might be obtained simply by running a solution of sodium iodide into the bladder.

DISCUSSION

Dr. H G. OGILVIE (Newcastle-on-Tyne) was absent, so his paper was read by the honorary secretary of the section. In the cases under his care in the Babies' Hospital the majority had urinary infection as the sole lesion, but in over one-third it was part of a general sepsis The onset was often acute with

violent vomiting, pyrexia, convulsions, refusal of food and development of the "gastro enteritis syndrome" In other cases the onset was more insidious, the infant becoming fretful, drowsy and losing weight. In these cases there was a peculiar earthy tint of the skin which often gave a clue to the diagnosis Acute abdominal pain, especially in older children, might lead to the diagnosis of acute appendicitis Further, pus might not be present in the urine during the first few days In treatment he found potassium citrate in infants did not give good results It often caused gastro intestinal upset Sulphanilamide, and especially M & B 693, were much more satisfactory In renal tuberculosis symptoms were often absent and the general health fairly good Tuberculous cystitis was invariably secondary to renal tuberculosis The prognosis should be guarded Even after a successful nephrectomy, blood stream infection might occur with a terminal meningitis

Dr ALAN MONCRIEFF (London) said that among 300 cases of dehydration fever under his care at Queen Charlotte's Hospital, the relief was so rapid when these infants were given fluid that he could not believe that the fever was caused by urinary infection or pyelitis In urinary infection a recurrence might be brought about by insufficient fluid intake, the injudicious use of purgatives and upper respiratory infection Acute *B coli* fever was like typhoid fever and sometimes the spleen was palpable When hourly records of the reaction of the urine were kept there was no correlation between the alkalinity and the fall in temperature

Dr K H TALLERMAN (London) said that it was his practice to give ½–1 oz of fluid before each breast feed during the first few days of life This had reduced the incidence of pyrexia in the neonatal period Dehydration fever was particularly liable to occur in large infants who, because of their size, got insufficient fluid He agreed that dehydration fever was not due to urinary infection

Prof G B FLEMING (Glasgow) stressed the importance of urinary stasis and referred to the high incidence of gastro enteritis in urinary infection He was convinced that in older children the lesion was often simple cystitis which cleared up with alkalis in a very short time

Dr FRANCIS ALLEN (London) said that a sustained temperature in the neonatal period often meant pyuria, and if frequent catheter specimens of urine were examined, it was surprising how often a *B coli* infection would be found In cases with chronic pyuria, repeated attacks might be secondary to an infection elsewhere such as the respiratory tract Dr JOHN CRAIG (Aberdeen) drew attention to the initial septicæmia and to its connexion with acute bowel infections

In reply, Dr SHELDON said he was sorry if he gave the impression that dehydration fever was not a definite clinical entity The point was that one should be careful in making such a diagnosis Fluid would relieve the pyrexia but in an infant with a raised temperature for 3 to 4 days it was unsafe to make a diagnosis of dehydration fever The cause was then usually to be found in the urine

The Physically Subnormal Child

Dr ERIC DOTT (Edinburgh) said his conclusions were based on a group of 70 children seen at the outpatient department of the Royal Edinburgh Hospital of Sick Children who showed a slightly subnormal physical constitution These children became too easily fatigued when facing the wear and tear of ordinary home and school life They presented many and varying symptoms of fatigue, including digestive, circulatory and nervous upsets They were handicapped at school and were repeatedly under treatment for various complaints The recurring symptoms caused much anxiety, both in parents and child. The important point in management was that there should be an endeavour to assess these children's capacity and to adjust their activities so as to avoid fatigue This guidance and control had to extend over several years and periodical adjustment was necessary Enough physical and mental rest was essential, if necessary school hours must be curtailed and hours of activity redistributed, diet must be adjusted to suit the child's digestive capacity and to include adequate fresh foods and vitamin B_1, a cheerful and confident atmosphere around the children must be aimed at Full coöperation of parents and education authorities was essential A regime of this nature had been applied in the 70 children mentioned The follow-up showed that symptoms of fatigue could be greatly lessened and a much happier life for child and parents could be obtained

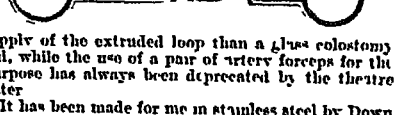
Child-psychiatry and Pædiatrics

Dr ETHEL DUKES (London) put forward a plea for closer understanding between pædiatrics and child-psychiatry The family doctor was often the first to be consulted for behaviour problems and other psychological disorders, and he could consider the patient as a whole and could fully evaluate its environment It was also possible that various organic diseases in children might be but the organic end of functional disorder Psychic conflict or tension might bring about a state of malassimilation and malnutrition in spite of an adequate diet In the so called problem children, nervous complaints and somatic disorders were prominent features, the family doctor and the pædiatrician were more nearly concerned in the first place. The family doctor should be able to diagnose and treat minor psychological disturbances, and often he was the only person who could bring about the necessary environmental changes Just as the general practitioner and the pædiatrician should develop the psychological approach, so the child psychiatrist should have experience of children's medicine and normal children before he commences his special training

New Inventions

COLOSTOMY TRANSFIXION PIN

THE pin and cap here illustrated may be found useful by surgeons who employ this particular technique It is handier and less liable to damage the blood-



supply of the extruded loop than a glass colostomy rod, while the use of a pair of artery forceps for the purpose has always been deprecated by the theatre sister

It has been made for me in stainless steel by Down Bros Ltd, of St Thomas's Street, S E 1

T. B MOFFAT, F R C S

"When a thing is old, broken, and useless we throw it on the dust heap but when it is sufficiently old, sufficiently broken, and sufficiently useless we give money for it, put it into a museum, and read papers over it which people come long distances to hear"—SAMUEL BUTLER in his note-books.

REVIEWS AND NOTICES OF BOOKS

Facts About Food

By S HENNING BELFRAGE, M.D. Lond. London. Humphrey Milford, Oxford University Press 1938. Pp 177. 3s. 6d.

Food, Health, Vitamins

(8th ed.) By R H. A. PLIMMER, D.Sc. Lond., professor of chemistry in the University of London at St. Thomas's Hospital; and VIOLET G PLIMMER London: Longmans, Green and Co. 1938. Pp 233. 5s.

Food, Facts, and Diet Planning

By GRACE MACDONALD, B Sc., F.R.I.P H., head of the science department, College of Domestic Science, Atholl Crescent, Edinburgh. London: Macmillan and Co. 1938. Pp. 168. 3s.

Sun Diet

By T. H. SANDERSON-WELLS, M.D. Lond., F.R C S.E., consulting surgeon, Weymouth and District Hospital. London: John Bale, Sons and Curnow. 1939. Pp. 100. 5s.

WHY do people write books about food? Here are some possible reasons. A publisher has suggested it, a teacher feels he ought to be an author, authorship may be a step towards a post as a teacher Those devoid of self-interest are perhaps suffering from a repressed complex which must express itself—in other words a *cacoethes scribendi* We suggest that no-one should write a book on dietetics unless he has done some research in the subject, unless he knows his subject, both qualitatively and quantitatively, unless he has a sceptical but none the less commonsense type of mind, and finally unless he has outlived the intellectual sloppiness of youth

Only one of these books successfully passes these tests The first author fails to be quantitative "Meat is a good source of vitamin B" he says on p 87 He is inaccurate · "The *carrot* is a good source of vitamin D or its precursor carotene and *also of vitamin A*" (p *101*). And he is very vague The third volume is also non-quantitative and gives no evidence that its author knows her subject "Some of the amino acids of proteins are," she says, "more important than others and they must be *joined up in the proper order*" (p *34*). Chapter VI is headed "The Large Intestine a Laboratory of Disease" The fourth volume is dogma without backing *Biblia abiblia*

Professor and Mrs. Plimmer's book is now in its eighth edition and, like good wine, needs no bush to advertise it. It has obviously met a need. To so well established a friend, criticism must be a compliment. Do the Professor and his wife really intend the implication contained in this sentence on p 3 · "Incidentally cancer and diabetes, two scourges of civilisation, have increased proportionately to the sugar consumption"? And what are we to say of the statement that "*Cow's milk and green vegetables* are the chief sources of calcium" (p 38)? Many fish (see McCance and Shipp and p. 216 of the book itself) are better sources of calcium than most green vegetables except spinach, and in spinach the calcium is unavailable because of the oxalate present. In considering the effect of canning upon vitamin C it would be fair to mention Miss Olliver's work. The footnote on p 72 reads "Levo-rotating polarized light to the left" This does not help the layman and sets the teeth of a physical chemist on edge The relatively large amounts of vitamin B_1 in pig products do not receive mention on p. 94. And on what grounds do the authors say that in boarding-schools there is a prevalence of constipation? Statistics please! In spite of these blemishes (and a certain air of crankiness) the book may be recommended to those who can sift chaff from wheat, or better, bran and germ from endosperm

Genetics and the Clinician

By LINDSAY RIDE, M A, B M. Oxfd, professor of physiology, University of Hong-Kong. Bristol: John Wright and Sons 1938. Pp 116 10s. 6d

RECENT progress in the science of genetics has been made chiefly in the fields of experimental breeding and cytology *As it is impossible to conduct breeding* experiments in man, our knowledge of human genetics has necessarily been gained by indirect methods The familial incidence of certain physical and mental characteristics is observed to correspond generally with the ratios which we have learned to expect from animal and plant experiments How far can the knowledge thus gained be applied to the prevention of human infirmities? Professor Ride gives a complete answer to this question in a well-written and instructive book It is valuable for what it omits no less than for what it includes. The reader is introduced to the principles of mendelism as observed in the pea and to those of chromosome behaviour as illustrated by the fruit fly Then, in chapters which deal with genetical ratios in human pedigrees, anthropological physiology and the inheritance of blood-groups, these data are applied to man There is a final chapter describing *possible methods of advancing the study of human* genetics and the book ends with a useful glossary

Professor Ride has the gift of lucid and forceful writing He succeeds in making both intelligible and interesting such complicated processes as linkage and *crossing* over of genes, independent assortment of genetic character and the confusions which have arisen in the description of human blood-groups If his recommendations as to the teaching of genetics in medical schools were carried out, this volume would well serve the purpose of a textbook for use in the preclinical period

Physiotherapy in Medical Practice

By HUGH MORRIS, M D. Belf, D.M.R E., consulting radiologist to the Devon Royal Hospital, Buxton; radiologist to the Salford Royal Hospital and the Royal Manchester Children's Hospital. London: Edward Arnold and Co. 1939. *Pp. 270. 12s 6d*

Dr Morris says that he writes for the practitioner *who has no specialised knowledge of electrotherapy*, and his exposition is clear enough for the beginner The subject matter is necessarily condensed, but Dr. Morris has included an amazing amount of practical information. The only chapters that suffer from excessive compression are those on diathermy and ultraviolet treatment In the former the value of diathermy in improving the circulation and aiding growth in paralysed limbs deserves to be mentioned. and in the latter the excellent results obtained in surgical tuberculosis are not sufficiently stressed, the contraindications and risks of treatment are merely indicated and the grave danger of submitting cases of active pulmonary tuberculosis to routine treatment are not sufficiently emphasised. The chapter on infrared treatment is an able summary of the present position, in which *current fallacies have been avoided* The book deserves a place on the shelves of every practitioner and of every electrotherapeutic department

THE LANCET

LONDON SATURDAY, SEPTEMBER 16, 1939

SOMETHING BETTER

THOSE who followed the deliberations of the seventh International Genetics Congress, reported in more detail on p 663, felt it had something of a symbolic significance Five hundred and sixty delegates, representing thirty-three countries, had met to debate the contributions of forty fruitful years to the youngest of the biological sciences Five hundred and sixty enthusiasts, no longer iconoclasts, were thinking in terms of pure botany and zoology, the age-old crafts of plant and animal breeding, and, not least, of the scientific betterment of man himself They were men and women animated for a time by an international spirit Their only racial distinction was a specially warm welcome for the contribution of a delegate from a country other than their own In spite of the wishful thinking that has taken the place of observation and deduction in the all-highest medical circles of Germany, the papers of the German delegates were listened to with interest and appreciation The congress had the benefit of their presence for a single day only before they were recalled

Genetics is no longer a novelty, promising sudden revelations or revolutions in scientific thought, it has settled down as a well-established branch of biology with its own laws, principles, and technique A biological science so well established must have a definite contribution to make to medical education and practice The General Medical Council has recommended that special attention should be paid to genetics during the preclinical years, presumably because it helps the student to understand the transmission of hereditary abnormalities, and the part played by inborn predisposition in disease To the average medical student and for that matter to the average doctor, genetics is still an obscure and academic subject, quite unconnected with the wards and the outpatient departments The proceedings of the congress showed clearly, for the first time, that there does exist a science of human and medical genetics, different from the genetics of the textbook and the laboratory Unlike the drosophila or the guinea-pig the human species cannot be artificially mated and it would need a Methuselah to follow out the effects of human mating Instead one has to observe conjunctions apparently made at random The problems presented are quite straightforward but are not set out in the usual textbook form Special mathematical methods are required It is however, fortunate that while the precise methods of computation may be intricate and not as yet fully agreed upon what the mathematician is trying to do is obvious enough It could in fact be explained in the wards far more easily than many a problem in practical bacteriology

Medical genetics is really a part of general medicine, with applications to the other clinical subjects, and not least to preventive medicine The ideal is for the student to receive practical teaching in genetics during his ordinary instruction in the wards and special departments A case of hereditary disease or abnormality might form the text for a discussion which would start with a reminder of the basic principles of the subject, and then apply these principles to the individual patient, the family group, and the population at large Two of the special departments, the ophthalmological and the dermatological, get more than their share of hereditary abnormalities, and they might well serve as reservoirs of teaching material When medical education once more settles down to an ordered routine, it would be a reminder that after war comes peace and rebuilding, if a few clinical lectures on genetics illustrated by patients, could be squeezed in Genetics may seem a luxury in war-time It takes many years to grow a man It is quicker to kill him than to cut down a tree In our preoccupation with destruction, genetics reminds us that the only justification for slaughter is a determination to build something better in its place

CLOSED 'METHOD OF TREATING WAR WOUNDS

SINCE 1918 war surgery has not stood still, but has marched on, as it were, in mufti Although great advances were made in the treatment of wounds and fractures during the last war, perfection was still far distant when it ended The subsequent years of comparative peace have provided an opportunity for consolidating the positions reached and for further developing methods that were being evolved For example, the one devised by WINNETT ORR for the treatment of infected open fractures has been applied to the treatment of osteomyelitis and is now widely used with various modifications On a smaller scale the possibilities of what is known as maggot therapy have been explored, as is recalled by a letter in our correspondence columns this week Recently too, the war in Spain has given surgeons the opportunity for testing new methods in circumstances that presumably resemble those we may expect to meet in the coming months or years Dr JOSEP TRUETA had 2½ years' experience of surgery in Barcelona during the Spanish war, and valuable lessons may be learnt by considering the technique he evolved for the treatment of war wounds and fractures This technique, already described in our columns,[1] is set out in more detail and with some interesting photographs in a small book published last week.[2]

What are the theoretical requirements for a

1 Trueta, J *Lancet*, 1939, i, 1152
2 Treatment of War Wounds and Fractures. By J Trueta M D late director of the department of surgery General Hospital of Catalunya Barcelona London Hamish Hamilton Medical Books 1939 Pp 144 5s 6d

system of treating war wounds and particularly those sustained in air-raid casualties? A standard method that can be adapted to a great variety of injuries is desirable it must deal with the results of both trauma and infection; it must be rapid, the instruments and apparatus used should be simple and few; the injured part should be immobilised in such a way that the patient can be transported away from the danger-zone as comfortably and as soon as possible; and a minimum of nursing and dressing should be necessary. TRUETA'S system fulfils most of these requirements. His first step consists in "débridement" of the wound, which is a thorough excision of all contaminated and damaged tissue, especially muscle, together with the removal of all foreign bodies (unless they are inaccessible) and the opening up of adjacent cellular spaces. Any associated fracture is then reduced, the wound is firmly packed with dry sterile gauze, and the limb is encased in plaster-of-paris which, in the absence of complications, is left in place for two or three weeks; only in exceptional cases is the wound sutured. It will be observed that no part of this system is in itself original, débridement is now generally practised although it is often followed by primary suture, and to pack the wound and encase the limb in plaster is simply to apply to recent wounds WINNETT ORR'S method for treating infected fractures. The result is a method of treating wounds and fractures that is certainly simple and fairly speedy. It can be adapted to many different sorts of injury, and it requires no special apparatus The aim is to prevent infection, but if infection develops it remains localised and, so far as the body is concerned, external. The broken limb is immobilised and the patient is in ideal condition for being transported The wound requires no further attention for two or three weeks Last but not least, the treatment appears to be successful in saving both life and limb TRUETA claims 90 per cent good results and only 0 5 per cent deaths in over a thousand cases of open fractures

This so-called "closed method" has, however, several serious disadvantages Perhaps the most important is that the progress of the wound cannot be watched Serious complications such as gas-gangrene may develop under the plaster, and consequently they may be diagnosed and treated too late TRUETA'S answer is that such complications seldom arise if the débridement has been skilful and thorough, and that when they do occur they can usually be diagnosed, or at least strongly suspected, without inspection of the wound. Danger-signals are deterioration of the patient's general condition, a rapid pulse, local pain, and œdema of the extremity beyond the plaster; in these circumstances the plaster should be at once removed. But this answer is not altogether satisfactory It may be hard enough to diagnose early gas-gangrene when one has all available evidence, local and general; how much more difficult will it be when the wound is encased in plaster. And to remove the plaster in every slightly suspicious case would be to waste much time and often to interfere unnecessarily. Presumably it is only after much experience of this technique that the surgeon learns to interpret correctly the early signs of serious complications Another big disadvantage is the stink, which sooner or later becomes intolerable both to the patient and those near him Apart from general ventilation, no effective counter-measure has yet been devised except to change the plaster and the packing, and to do this frequently defeats one of the most important objects—namely, uninterrupted rest A further difficulty that will sometimes be encountered is that plaster-of-paris is far less effective than continuous traction in controlling deformity in those fractures in which there is shortening maintained by muscular spasm. Despite these faults, however, it is obvious that this method has much to recommend it, and we believe it should be seriously considered by those now responsible for the treatment of air-raid casualties

WHERE CELL TOUCHES PLASMA

THE combined surface of all the red blood-cells in the body is said to be about 3,000 square metres, and its importance in respiratory exchange is obvious On another page Professor FAHRAEUS of Uppsala presents it to us in a new light as something intimately concerned with the life and behaviour of the erythrocyte itself It is not, however, the exclusive property of the cells; it belongs equally to the plasma and is more correctly designated by the term "interface." Its dual significance is proved by the fact that when it is removed, as by segregating corpuscles and plasma, changes occur in both The physical and chemical nature of these changes is unknown, but they both reduce the agglutination and sedimentation time of the red cells and reinforce each other. FAHRAEUS and his colleagues have devoted their attention chiefly to the alteration in the plasma; they postulate the formation, by an enzymic process, of a lecithin derivative similar to that found in cobra venom. Having formed spontaneously in separated plasma, the substance can be removed by suspending erythrocytes for a time in the plasma, and it is therefore held to be adsorbed on to the surface of the cells The cells, besides losing their tendency to form rouleaux (and thus to sediment), then become more spherical, this deformity being associated with an increased tendency to hæmolysis. Since erythrocytes which have been separated for some time tend spontaneously to the same end, and since the spleen is a place where such separation occurs, a plausible theory of blood-cell destruction at once emerges, and is supported, as FAHRAEUS points out in his review, by evidence of increased susceptibility to hæmolysis of cells thrown into the circulation from the splenic stores.

Until all the factors have been thoroughly worked out, the theory must lack precise formulation, but of the significance of the work on which it rests there can be no doubt The experiments have the simplicity of genius It is abundantly clear even at this stage that they will ultimately throw light on many pathological, and it may be on

some metabolic processes The evolution of the research is a striking example of the way in which work in one field will dovetail into that in another, apparently unrelated Not content with his now familiar observation that the sedimentation rate of the blood-cells is greatly increased in pregnancy and certain pathological conditions, FAHRAEUS established agglutination as the cause and examined the various factors controlling this They are numerous, and among the chief seem to be the concentration of globulin and fibrinogen in the plasma, these substances, it is suggested, tend to neutralise the negative electrostatic charge carried by the corpuscles which normally maintains them in a state of mutual repulsion

One of the most fruitful lines of inquiry was the relation of stasis to agglutination, leading directly to an appreciation of the important of BARCROFT'S work on the reservoir function of the spleen and its possible physiological association with prehæmolytic changes KNISELY'S analysis of the splenic circulation suggested to FAHRAEUS'S quick mind that since stasis must be associated with a reduction of the erythrocyte-plasma interface, this surface change and not the mere lack of mobility might be determining corpuscular deterioration Put to the test, this inspiration proved to be well founded and led on to the possible solution of other problems FAHRAEUS suggests that reduction of the interface may not be a local affair concerning only the spleen, where a special mechanism operates to separate the cells from the plasma, but may be significant in conditions such as anæmia and those in which rouleaux-formation occurs in the general circulation To the uninitiated it might seem that this condition would tend to correct itself, since one of the signs of corpuscular damage is a diminished tendency to agglutinate, but FAHRAEUS thinks this tendency is masked by the powerful agglutinating influence of such factors as increased globulin concentration His experiments certainly make it probable that the anti-agglutinative properties conferred by plasma-separation are by no means negligible, and must lead us to inquire how far the spleen contributes to the normal suspension stability of the blood

ANNOTATIONS

DIAGNOSIS OF SHOCK

AT the present time the early diagnosis of shock is of the highest importance, for it is only in the early stages of shock that treatment is of any value Now that blood transfusion services have been organised it has become more necessary than ever to differentiate between hæmorrhage which requires transfusion, and shock in which there is already an excessive concentration of the red cells On another page Mr Layton suggests some guides to practice in dealing with abdominal wounds Moon,[1] from published observations and his own experiments, demonstrates that the earliest sign of impending shock is a rising concentration of the blood as revealed by hæmoglobin estimation by red cell counts and by determination of the specific gravity of the blood Hæmoconcentration often takes place even when the blood-pressure is *rising*, but if this happens a subsequent (possibly fatal) fall in blood pressure can be prophesied with certainty In hæmorrhage, on the other hand a mechanism is at work which tends to restore the blood volume to normal by absorption into the circulation of tissue fluids, this results in dilution of the blood and falling hæmoglobin values and red cell counts A difficulty is encountered when shock and hæmorrhage coexist, here owing to the loss of red cells the hæmoconcentration is comparatively slight in relation to the clinical signs of shock A hæmoglobin estimation though not considered is reliable as a red cell count is the quickest means of verifying the existence of excessive concentration of the blood and treatment of the wounded can readily be based upon its result Thus a falling hæmoglobin indicates the need for blood transfusion, whereas a rapidly rising value shows the need for anti-shock measures such as "forced fluids" by mouth or rectum Plasma transfusion—an attempt to maintain the plasma volume, and a more or less stationary hæmoglobin percentage, in the presence of obvious clinical signs of shock—represents a combination of the two forms of treatment

PROGNOSIS IN PREMATURITY

THERE are many difficulties in any large scale follow up study of prematurely born children, not the least of which is the tendency of parents to move house after an increase in family, especially when this is the result of a first born R S Illingworth has surmounted this difficulty however in an ingenious fashion, relying upon the well known memory of mothers for the birth weight of their offspring He has kept records of 152 consecutive children above the age of one year who at birth weighed 5½ pounds or less irrespective of the alleged duration of gestation, and compared them with similar records of 152 consecutive children who at birth weighed 8½ pounds or more The children were attending the outpatient department of the Hospital for Sick Children, Great Ormond Street, for a wide variety of ailments, all, irrespective of ailment, were included in the series except for four, two in each group, who were suffering from such a gross defect as to make their inclusion unprofitable Illingworth records[1] the results of his studies in various ways, the most important being concerned with the effect of birth weight upon the weight chart Previous studies had suggested that the weight curve of prematurely born infants tended to catch up to the normal at about the age of four years. Illingworth finds, however, that in his series 86 per cent of all the premature infants were under weight at all ages (1 to 12) and only one child in the whole series of 150 fell into the 5 pounds or more overweight group Actually the control series showed 34 per cent underweight but most of these were within 5 pounds of the normal whereas over 21 per cent of the premature series were 10 pounds or more underweight as compared with 1 33 per cent of the control series Illingworth concludes that prematurity must be considered as a common cause of dwarfing and that weight charts which do not take into consideration the birth weight are useless for dealing with the expected weight of any individual child

Another comparison made was concerned with the

1 *Arch Dis Child* 1939 14 121

COLLEGE

incidence of infectious diseases in the two series, since it might be expected that the premature child, being more "delicate," would be more liable to infection than the child of normal weight at birth. Actually he found no difference in the incidence of the infectious fevers in any of the age-groups examined With regard to evidence of cerebral defect however the prematurely born (or, more strictly, the underweight) infant scores badly. The incidence of spasticity, mental deficiency and athetosis was compared in the two series and found to be much higher in the underweight group Gross mental defect, fits or athetosis were present in 20 per cent of the premature group as compared with 6 7 per cent of the control group. Obviously this must not be interpreted as applying to premature infants in general, since Illingworth is dealing with patients brought to hospital because of some disease or defect, but the fact that evidence of cerebral defect is present three times more often among the infants who were small at birth contains food for thought for the obstetrician. A further finding showed an opposite result, so to speak, for the figures for asthma showed that there were nine times as many cases in the control group as in the premature group, and in a small series of cases of infantile eczema also examined only one out of fifty had been below 5½ pounds in weight at birth.

It is clear that there are many factors which may contribute to a low birth-weight—financial status of the mother, her diet during pregnancy, hereditary factors and pathological states of pregnancy—and certain of the findings in Illingworth's study may be related to other causes than mere smallness of size at birth His work should stimulate those with access to similar records, for example among the well children attending welfare clinics or among the records of the school medical service, to sort out some of the points still requiring elucidation. The mortality-rate among premature babies is appallingly high. would its reduction mean the saving of a group of weaklings? Illingworth has supplied some of the answer, but we want to know the rest.

GERMAN MEDICINE IN THE LAST WAR

Prof. A. Waldmann was head of the army medical service on the German side during the years 1914–18 and it may be of interest to look at the achievements of this service through his eyes Five years ago, fearing that the events of twenty years earlier were becoming unreal and almost legendary in the minds of the younger generation, he promoted a special number of the Munich medical journal[1] dealing with every aspect of military medicine and himself contributing a foreword He tells us that of the 26,292 military doctors 1783 (6 8 per cent) lost their lives, the proportion naturally being highest (10 per cent) among the doctors at the front. They handled in all 27 million wounds and illnesses, of which 98 4 per cent. survived and 95 8 per cent became again fit for service These convalescents numbered on the average 67,000 men a month, or almost one half of the supply of fighting material Waldmann estimates that the new hygiene and surgery kept alive a quarter of a million men who would otherwise have been lost Actually some 40 per cent of the men in the field were at no time ill or seriously wounded The mortality from wounds was ten times that from disease and he contrasts this proportion with that of 5 to 1 in the Franco-German war and 1 to 6 5 (note the reversal) in the earlier wars of the nineteenth century On the western front the incidence of typhoid was seven times less in 1914–18 than 1870–71 and a quarter as fatal Smallpox and cholera had no footing, their place being taken by infectious jaundice, five-day fever, and trench nephritis, and he remarks on the curious fact that not only did diabetes and gout disappear "for the duration" but also scarlet fever. Venereal disease never reached its peace-time figure and was only 7 per cent. in the whole army Experience gained in gas warfare had found useful application in industry and sanitation, and finally life in the field was the basis of a life lived closer to nature among the growing generation and had given birth to a new specialty of sport medicine Waldmann concludes with the remark. "Military medicine also, by its fruitful contribution to medicine as a whole, obeys the law that war, in the sense of necessity, is the father of progress in human endeavour."

EXPERIMENTAL CANCER OF THE LUNGS

THE apparent rise in the incidence of human lung cancer makes it imperative to follow all clues available from experimental work concerning its cause Although the rise cannot yet be satisfactorily explained, a number of relevant facts have come to light It is now known that lung adenomata are the commonest of all spontaneous tumours in mice, that all stocks are afflicted to a greater or less extent, especially as the individuals grow old, and that a susceptibility is inherited as a mendelian dominant All experimental observations have to be interpreted in the light of this knowledge It has also been found that the incidence of these adenomata can be raised by the application of tar, or pure chemical carcinogenic substances, to the skin of mice, without necessarily producing a skin tumour at the same time, that is to say, the tumorigenic effect is seen in an organ remote from the point of application This might indicate that, in seeking the cause of the human lesion, carcinogenic substances should be suspected in sources other than those that can reach the lungs with air—for example, in skin creams that are used regularly Some doubt has now been thrown on such an interpretation, however, by an experiment recorded by Magnus.[1] In an attempt to produce gastric carcinoma in mice by injecting 1 : 2 5 . 6-dibenzanthracene, dissolved in olive oil, through an ingenious adaptation of the stomach-tube, he succeeded unexpectedly in raising the incidence of lung adenomata of his market stock from about 4–8 per cent to 95 per cent. without producing any neoplasms in the stomach. More unexpected still was the unusual finding that 75 per cent. of these adenomata became malignant. The conclusion might have been drawn that here was another instance of a carcinogenic agent acting on the lung from a distance. Magnus, however, went on to test this supposition He delivered similar meals, some containing charcoal and some containing carmine, into the stomachs of mice, and on killing the animals at successive intervals found coloured particles in the smaller bronchi and alveoli This makes him think that in the previous experiment, despite absence of trauma, very minute quantities of the carcinogen accidentally reached and lodged in the respiratory tract According to his calculation the total dose reaching the lungs in six months might have amounted to between 13 and 26 mg It has already been suggested by Argyll Campbell[2] that when lung tumours follow painting of the skin with tar, the tar dries and flakes and is

1 Magnus, H. A., *J Path Bact.* 1939, 49, 21.
2 Campbell, J. A., *Brit J exp Path* 1934, 15, 287.

in fact inhaled as small particles by the mice Campbell[3] has shown also that road dust with a content of only 2 per cent of tar is capable of raising the lung tumour rate from 8 to 80 per cent when mice are subjected for long periods to an atmosphere containing it The active agent in such a dust would probably be very dilute It thus appears that by whatever route the carcinogenic agent reaches the lungs, whether directly with air or indirectly by the blood-stream, the effective dose may be extremely small

COST OF MINIATURE RADIOGRAPHY

THE miniature radiogram as an adjunct to routine physical examination was mentioned in one of our leading articles a fortnight ago, in discussing the death of a militiaman from pulmonary tuberculosis a few weeks after being passed as fit Now A Robinson Thomas[4] has described in detail a simple set up prepared for him by Watson and Sons of Parker street, W C 1 If ordinary 12 × 15 in direct films were used, the outlay on examining 1000 men would be £100 since these films cost about 2*s* each Using 35 mm film mine photographs can be taken on 1 foot of film, and 10½ feet of this film cost 8*s* 10*d* at ordinary prices Using miniature photography, therefore, the cost for 1000 men would be about £2 8*s* The cost of the apparatus used by Mr Thomas, including special developing tanks, screening stand, lightproof cone, miniature camera and lens and also a special projector and screen is about £650 As soon there fore as 7000 pictures have been taken the capital expenditure on the new apparatus has been covered, and the enormous saving in running cost starts to show itself The method is extremely rapid, and Holfelder in his clinic at Frankfurt A M claims to be able to examine 400 cases an hour In Rio de Janeiro, de Abreu[5] is satisfied with 120 an hour Berner[6] has already examined 55 666 patients of whom 32 360 were soldiers and 10 532 picked storm troopers Among the latter, 0 8 per cent was found to have active tuberculosis, while among the German police 1 68 per cent were found by the same method to be infected In spite of mechanisation, personnel is still the most important thing in an army, and miniature radiography can scarcely be excluded from making its contribution to the health of our newly recruited forces on the grounds of expense

THE SOUTH AFRICAN DOCTOR

ACCORDING to Dr Dru Drury[7] there are three defects in the South African medical profession Firstly there are too few doctors There is one practising doctor for every thousand of the European population but if coloured and native population are included, the ratio becomes one doctor for every five thousand Secondly the distribution is faulty One fifth of the Union population live in nine large cities, but this fraction has attracted half of the available doctors Cape Town has one doctor for every four hundred people, while the Transkei has one for thirty thousand natives Lastly medical care is too expensive White doctors fail to settle in native areas, yet Dr Drury says that when the Rockefeller Foundation offered to found a medical school on the Rand for training native doctors the offer was turned down, and natives are not admitted to medical degrees in the existing universities But of the need for a widening of medical practice the recent annual report of the M O H for Cape Town leaves no doubt He writes

> "The social and economic conditions of the Cape Coloured are on the whole unsatisfactory The principle of compulsory education, which is applied to European children, does not extend to them, and although certain schooling facilities are available for them, in many cases of an inferior order, there is much illiteracy, and also a lack of discipline in certain classes of adolescents With a very few exceptions they belong to the working class A small proportion have skilled trades and receive satisfactory wages, but the majority belong to the unskilled labouring class These receive very low wages, usually not more than 30*s* a week when in full work, and often less The wages of the head of the household are commonly eked out by the earnings of his wife and children The City Council pays its labourers a minimum wage of £2 a week, but this is much above the local standard of wages In the building trade the minimum wage for labourers is 9*d* an hour The resulting poverty produces its inevitable result amongst the coloured people A large section of them suffer from malnutrition and their housing conditions are very bad Alcoholism is common and there is a high incidence of venereal disease The effects on their health are shown by the contrast between the vital statistics of Europeans and non Europeans "

The racial distribution of sixth year medical students in South Africa is interesting Jews make up 37 per cent, English 33 per cent and Afrikaans 26 per cent

THE PROPOSED TUBERCULOSIS RESEARCH UNIT

EVER since the discovery of the tubercle bacillus attempts have been made to influence the course of tuberculosis by germicidal drugs—but always without appreciable result Lately the success of surgical measures in cases proving refractory to regimen and diet has pushed the thought of chemotherapy into the background The position is now changed by the advent of the sulphonamide group of drugs, although it would be unwise to argue that they must be effective in tuberculosis because they have given such brilliant results in other infections But if chemotherapy is to find its place in tuberculosis it will surely be as a result of team work, the harmonious cooperation of bacteriologists, pathologists biochemists and clinicians For this reason we share the disappointment recently expressed in the *Times* at the decision of Middlesex county council not to adopt the proposal for a tuberculosis research unit The council has it seems approved the principle, but holds the view that it should be a national rather than a local service The proposal was to ask the Medical Research Council to second Dr Leonard Colebrook who is at present director of the research unit at Queen Charlotte's Hospital, to direct the new tuberculosis unit, bringing with him his own research team The salary of the director would have been paid by the council which would also have provided the raw materials of research from the Mill Hill laboratory Although no results could be guaranteed the establishment of a research unit such as that contemplated could hardly fail to yield information of therapeutic as well as of purely scientific value The record of the unit at Queen Charlotte's has been remarkably good We should like to see it made possible to achieve like results in another field Preoccupation with more obvious foes can be no excuse for wavering in our offensive against Osler's captain of the men of death

THE OTHER THIRTY-NINE MILLION

A LARGE proportion of the hospital beds of this country have been cleared for the reception of air-raid casualties, and a large proportion of the medical profession are waiting idle until these beds are filled. Meanwhile the size of the population has not diminished; there is as much illness as ever and in reception areas there is presumably more The Minister of Health recognises this fact, and last April he said it was not proposed in war to keep the ordinary hospital service reduced below its normal level for any length of time, the Ministry, he told a Birmingham audience,[1] had in mind that the ordinary inflow of patients displaced at the outset of an emergency would in a few weeks accumulate again, and would require hospital treatment, and must be catered for. The difficulty arising here is that in a few weeks' time the emergency proper may not even have begun; and until a full attack has been made on our cities, and an equilibrium of forces has been established, we must expect the worst and must not relax our essential precautions That brings up the question how far all the precautions are essential, and we submit that some revision is desirable even at this early stage. Is it absolutely necessary, for example, that London children, of whom perhaps half a million remain at home, should be turned away from the doors of our hospitals when there is an unoccupied staff inside that would gladly give them attention? We beg authorities, great and small, to permit the exercise of that gift for improvisation said to be one of the assets of our race The medical service of the country is largely and inevitably dislocated; but it is *not* inevitable that consent should be withheld for the small efforts made by intelligent medical men and women to supply the needs around them. The requirements of the reception areas will be met in due course, we are assured, by the transfer of practitioners whose work has disappeared. Meanwhile we see obstetricians and paediatricians, eating their heads off in rural hospitals, who are refused permission to start small informal child-welfare or antenatal clinics for the pregnant women and the children evacuated to the villages of the neighbourhood, with whom local doctors frankly cannot cope The Ministry of Health cannot be expected, for the present, to investigate and expressly sanction small undertakings of this kind; but hospital authorities and medical officers of health will deserve no sympathy if they thwart initiative and strangle schemes that will help even a few of the many persons now deprived of the medical help to which they are accustomed Nelson did not win by using his telescope to magnify the wording of the book of rules.

MEDICAL WOMEN IN THE SERVICES

THE actual number of medical women who served with the forces of the Crown in various capacities in the last war is not known, but it certainly amounted to many hundreds They were employed on the staff of the Endell Street Hospital in military hospitals at home and in Malta, Salonica and Egypt, and in the last year of the war with the Q M A.A C., the W R N S and the W R A F These groups of women were recruited under different contracts and with different rates of pay and emoluments, so that women in one group never knew whether concessions made to other groups applied to them or not and it was extremely difficult to take any combined action to improve conditions The main disability from which serving medical women suffered was the lack of commissioned rank, which left them without authority over their subordinates and led to obstruction in their professional work and frequent humiliation Those serving in military hospitals were not even allowed to wear uniform until March, 1918

Further, however long and meritorious a woman's service might be she was not eligible for promotion, but was liable to be superseded by any newly joined officer, and she was also not eligible for many of the allowances given to her male colleagues The refusal of the authorities to grant commissions to women was based on the view that they were not capable of performing all the tasks undertaken by medical officers, such as the command of field units and the inspection of recruits The Medical Women's Federation argues, however, that this also applies to male specialists, and that although it was a good reason for limiting the number of medical women employed in war service the utility of women would be no less if they were given commissions In March of last year the Federation stated their case in a memorandum[1] to the Secretary of State for War, and in July Mr. Hore-Belisha replied that "if a woman doctor be employed on military work it is considered that she would be given a grading which would rank with officers of the Army." Unfortunately this vague answer does little to settle the questions of rank, promotion, pay and allowances, uniform and the like which gave trouble before, and requests for further information have apparently been unheeded In this war it may be some time before medical women are employed in military hospitals, but they will undoubtedly soon be attached to the corps of women working with the Army, Navy and Air Force There are many problems connected with the hygiene and medical care of large bodies of women in camps and hostels which can only be dealt with suitably by doctors of their own sex As things stand there is no guarantee that women doctors employed in the Services will have any more definite status than they had in the last war. The conditions of employment should this time be categorically set out as they are in the case of men, so that women may have an opportunity of considering them in detail before accepting them

A MEDICAL LINK WITH SHAKESPEARE

IN 1607 Shakespeare's elder daughter Susanna married John Hall, a physician. Recent investigations have identified him with the John Hall, son of William Hall of Acton, who matriculated at Queen's College, Cambridge, in 1589, and proceeded to M A in 1597. He then went to France to study medicine, and eventually settled in Stratford, possibly as early as 1600. The master of Jesus, in a delightful little volume,[2] has put together a series of apparently unrelated facts which throw a little light on this somewhat obscure personage. He never took a degree in medicine at Cambridge and what induced him to settle at Stratford is unknown. But the master, who can build a pyramid on its apex as well as another man, surmises that his choice may have been due to the connexion of the Lucy family of Charlecote with some property in Bedfordshire which either adjoined that of the Halls or was actually owned by William Hall, the father of John Further surmises make John Hall the source of certain names in Shakespeare's text, for example that of Dr. Caius, and certain phrases peculiar to Cambridge, also of the French in The Merry Wives and Henry V. But surmises apart John Hall physician emerges from the skilful reconstruction of the master as something more than a mere nominis umbra

TREATMENT OF INOPERABLE ABDOMINAL WOUNDS

By T B LAYTON, D S O, M S Lond

SURGEON IN CHARGE OF THE THROAT AND EAR DEPARTMENT GUY'S HOSPITAL, LONDON

WHEN it has been decided not to operate on a patient with a wound of the abdomen, with or without involvement of the chest, treatment consists of an inhibition of peristalsis, rest in the semi-erect position, and the supply of the necessary fluid to the body

INHIBITION OF PERISTALSIS

The inhibition of peristalsis is obtained by giving nothing by the mouth and by the use of morphia Abstention by the mouth must be absolute It is not enough not to give food, no water or other fluid should be given. Anything put into the stomach causes reflex peristalsis The only thing the patient needs to swallow is his own spittle, and there is not much of that It should not be further diminished by the use of atropine, because the dry mouth is one of the things which require attention to secure rest, but only the irreducible amount of moisture to secure this may be introduced and it should not be acid, for the smallest amount of acid sets up peristalsis The moisture is better obtained by stimulation than by supply Barley sugar may be used or a flavoured glucose stick It is well to allow the patient momentarily to suck this at short intervals and not to put a piece within the mouth In this way relief of dryness is effected with a minimum of swallowed spittle Alternatively the old fashioned preparations of glycerin of borax or of honey of borax may be used, placing small quantities upon the tip of the tongue

This absolute stoppage of all swallowing must be considered the main treatment The inhibition of peristalsis obtained thereby is supplemented by the use of morphia by injection This must be used freely and fearlessly, but it is important to remember that its use must be watched and studied It is a weapon that must be used like a rapier and not as a neolithic club To place a syringe and a phial of morphia in a registered medical man's hands no more makes him a doctor than to put a full grained bat in a boy's hands makes him a Hobbs or a Grace One of the most wonderful exhibitions in therapeutics that I have known was when an experienced physician kept a patient out of pain for a fortnight with tincture of opium in doses of 4-5 minims at intervals of four to six hours. And so it should be with the wound of the abdomen At first a large dose may be given to ensure sleep after the mental strain Then it should be the aim to keep the patient in a stuporose state just free from pain This must be done by constant watching and judging The dose and the interval must vary each time It cannot be done by leaving routine doses to be given at stated intervals The fear of producing a morphia addiction must not, at this stage enter the mind It is a fight for a life When this is saved there will be a prolonged convalescence in which any tendency to addiction may be eradicated

REST IN THE SEMI-ERECT POSITION

The upright position was devised by Fowler in America The idea was to drain any infective material within the abdominal cavity into the pelvis where absorption is less there than it is from the region of the diaphragm and liver and where the antibactericidal properties of the peritoneum were said to be greater The position is, however, of as great value in wounds of the lung and in the bronchiolitis of influenza as it is in infective conditions of the abdomen, and with these lesions its value rests in the way in which the lowest and hindermost parts of the lung can become ventilated without undue muscular exertion It is probable that this is as important in lesions of the abdomen as the drainage into the pelvis The best position is not strictly upright The body from the shoulders to the pelvis is at an angle of 45° with the horizontal and with the vertical The hip, knee and ankle-joints being all flexed at right angles, the thigh leg and foot are at the same angle in alternate directions

In 1907 Lane, noticing that the patients tended to slip down in bed, put a pillow under the knees To two of its corners he tied pieces of bandage, the other ends of which he fixed to the head of the bed He thus anchored the pillow to the bed and prevented it from slipping towards the foot In this way he retained the patient in the desired position This is the origin of the appliance that subsequently became known as the Lane pillow The improvisation is still invaluable when this pillow or other appliance, known as a 'donkey,' is not available Without some such thing beneath the patient's knees no nurse ever has kept or ever will keep a patient in the desired position The use of this appliance has as a result of confusion of thought, fallen into disrepute of recent years This is because it has been almost entirely used for patients upon whom non-infective civilian surgery, often gynæcological, has been performed, and a high proportion of cases of thrombosis of the veins in the pelvis has accompanied its use This is not surprising The surgeon has interfered with the circulation of this region by division of vessels and with his ligatures, and the patient often middle-aged and stout, has remained in this position for three weeks Further, in these cases the surgeon does not need the absolute rest that is essential to the patients under consideration in this paper It is good for them to be moved from the very first and then with increasing range to move themselves If, then they slip down a bit they can be hauled up afresh by the lift of two skilled nurses But when absolute rest is required, this repeated hauling exhausts the patient When these patients have slipped down, it is distressing to see them They lie on the lower part of the chest, so that with every inspiration the whole of the trunk has to be raised before any air can be drawn into the lower lobes of the lungs Since the body cannot flex forward in the dorsal region an acute bend develops in the cervical region bringing the chin down and narrowing the upper opening of the chest, so that the jugular veins become compressed, and the retention of the blood in the head adds to the distress caused by its deficient oxygenation Sometimes nurses become indignant when told that they cannot keep a patient in the desired position without the retaining pillow or appliance. They think it is a criticism of their personal skill Fear of raising indignation in the heart of an individual nurse must not be allowed to endanger the recovery of the patient, for it is upon the absolute rest that this position ensures that after the inhibition of peristalsis, the patient's chance of recovery depends Its primary purpose is to prevent any infected fluids from trickling about the abdomen while the protective adhesions are forming, but it aids in that inhibition of peristalsis that has already been considered and it is also a valuable factor in the treatment of shock

Rest must be absolute The nurse must for the time being give up all her routine with regard to the washing of the patient and attention to the skin. This specially applies to the back where the development of bedsores must be risked In this regard there is an advantage in the donkey beneath the knees. Without it the weight

of the body drives the pelvis down the bed, rucking up the upper part of the gluteal region with the area of the buttock, so that lesions tend to arise at the junction of the upper part of the gluteal region with the area of the sacro-iliac joint. With the "donkey" the contact comes upon the hinder surface of the upper parts of the thighs as far up as the gluteal fold, the pressure is more widely distributed

In another respect also the "donkey" is conducive to rest. Many persons, especially in middle age, cannot rest comfortably with the knees extended They must bend the knees, and to obtain the flexion they either roll sideways or flex the hips Both of these cause movements, and the latter also cause the heels, on which sores may develop, to slip down the bed as the patient relaxes the muscles when dropping off to sleep. The result of this is that he wakes again with a jerk, and the much needed sleep is impaired

The same principle applies to the head and neck They must so be propped with pillows that the muscles of the neck are not in play to preserve the balance of the head If they are, the moment the patient drops asleep these muscles will relax and the head flop sideways or forwards, waking him up again; or the head will bend backwards, and there he will fitfully sleep with the mouth open and suffer the more from dryness of the mouth when he awakes. The profound sleep, which helps recovery so much, depends largely on this position of the head It is best for the neck to be slightly flexed The patient does not want to stare at the ceiling If the head is turned towards the entrance to the ward, he can open the eyes when anyone comes in and satisfy his curiosity without any movement In this position also the nurse can get the necessary attention to the mouth without undue movement. If, however, the patient wants to, he should be allowed to move the head If he is restless, he may be persuaded to keep the body quiet if he is allowed to move the head, and, if he will, the arms

In the acquirement of absolute rest some patients may be hindered by their sensitiveness to noise There are some persons whom any trivial sound keeps awake. For them the ear-plugs that are obtainable may make all the difference Without them they stare wide-eyed round the ward, with them they sleep soundly.

SUPPLY OF FLUID

The third requisite in the treatment of an inoperable abdominal wound is the supply of fluid to the body Primarily this is to prevent death from thirst, but it has its place in the treatment of shock.

The old distinction between shock and collapse is not made today, shock being the diminution of the difference between blood-pressure in the aorta and that in the venæ cavæ from a reflex disturbance due to excessive sensory stimulation, whereas collapse is a similar diminution due to the loss of fluid from the body or from its diversion into some part of the body from which it cannot be restored into the circulation. The important thing to remember is that with shock, as defined thus, time is a favourable factor once a decision has been made that nothing is to be done that will determine further shock If an operation is imperative, there is a race against time to diminish the present in order to enable the patient to withstand the further shock of that operation. In the cases under consideration no such further shock from operation is anticipated. There is therefore no race against time.

The absolute cessation of further sensory stimuli that we call rest, combined with the application of heat, is the essential treatment of shock Any attempt to hasten recovery may impede it. Every additional treatment of shock involves some disturbance which may do more harm than the treatment does good There is no doubt that there have been patients whose chances of recovery have been destroyed by an excessive business in the treatment.

Judgment becomes still more difficult when, besides the shock, there is also collapse, as defined above This may be due to loss of blood or to an exudation into the damaged tissues When loss of blood has been excessive and has been stopped, it is advisable to replace the lost fluid at once. There is no quicker method of doing this than by the mouth, but, by the nature of the case, this route is interdicted and also it is not known whether the bleeding has been stopped or not, so that we are dependent entirely upon the natural arrest of hæmorrhage Now, in its lesser degrees, shock is a part of this natural arrest It is therefore undesirable to bring the patient out of the state of shock too rapidly. It is true that there is a further loss of fluid, not out of the body but out of the circulation in the form of exudation into the damaged tissues, as they swell up, and into its cavity, as the peritoneum becomes inflamed. This loss of fluid is, however, gradual It does not need replacing rapidly. It must be forestalled by a slow but continuing supply This is best given through the rectum, but, although the technical apparatus for its administration has advanced enormously, the question of how long and at what rate it can be administered has been forgotten It is not generally recognised today that rectal infusion can be continued without cessation for a period of forty-eight hours or more at the rate of half a pint an hour In 1907 nurses were doing this with an equipment which consisted of a piece of rubber tubing attached at one end to the nozzle of a Higginson's enema syringe and at the other to a bent piece of glass The long arm of the bent glass went to the bottom of a pint measure containing saline, and this stood in a bowl containing hot water to keep the saline warm The hot water was replaced from time to time and the saline refilled from hour to hour. The bowl stood upon the locker by the bedside, raised 12-18 in. above the level of the bed What her mother did with this crude appliance thirty years ago the nurse of today can do with her modern apparatus, once she is told that it is possible and has it made clear that it is demanded of her.

LATER TREATMENT

The rest, the warmth, the morphia and the rectal infusion may be tried for six hours after the patient is in bed If at the end of that time there is any improvement it may be continued If the patient is barely holding his own or there is a set-back, then is the time to decide whether the saline is to be increased by injection into a vein or supplemented by transfusion of blood And so the treatment should continue for three days. It is then that the absorption of twelve pints a day by the rectum may have begun to fail, and it is then that injection into the subcutaneous tissues either into the axilla with a needle through the pectoral muscle or into the submammary tissue may be of value. It is then also that the giving of food must be begun, and for this administration by the mouth is necessary. It still should be such that the peristalsis set up by it is minimal, and therefore anything containing extractives or a residue must be avoided, and it must not be hot A thin gruel at body temperature with sugar added, or albumin water with some glucose may be used The quantities given at first must be small One way is to give a teaspoonful every minute for an hour by the clock, by which time the patient will have had some 8 oz. of the fluid It is not necessary to have a trained nurse for this; a convalescent patient or a relation may do it; but it is necessary to have a watch, or too much will be given; and it is necessary to have the head slightly bent and turned to the side to

avoid any movement that will tire the patient by the frequent offerings of the spoon After this time larger quantities may be given at longer intervals, but rules cannot be laid down, for the doctor and the nurse must feel their way If this treatment be carried out, the nurse will never have to disturb the patient for from five days to a week, except for the passage of urine or possibly for the opening of the bowels, but this is likely not to occur if the peristalsis has been completely inhibited

At the end of a week it will be known whether the patient is likely to recover or not and the treatment becomes more active But one thing is certain at this stage he must not be moved

HUMAN GENETICS

As noted by our Scottish correspondent on Sept 2 the seventh International Genetics Congress opened in Edinburgh on Aug 23 The papers covered an enormous range of subjects, but those dealing with human genetics will be of greatest interest to our readers

Dr I LUNDHOLM (Ostersund, Sweden) discussed the *cause of hypochromic anæmia* He said that as a result of his researches he had come to the conclusion that underlying the disease is a simple dominant gene, the effect of whose presence is to impair the absorption of iron from the intestine In some persons the defect never becomes manifest, but if there is a loss of blood, anæmia follows owing to the slow absorption of iron The regular loss of blood during menstruation amongst women or reproductive age is sufficient to produce the anæmia in bearers of the gene, it is therefore seen very largely among women aged between 15 and 50 Men who bear the gene do not suffer from the disease nearly so frequently, amongst those who do there is often a source of hæmorrhage such as an ulcer or hæmorrhoids In some cases there is no apparent source of bleeding; it may be that in these persons the gene combines with such factors as lack of vitamins or infections

In a session devoted to *statistical methods* in human genetics, it became clear that the refinement of mathematical techniques has proceeded very far The difficulties inherent in the study of human material can be largely avoided if data are collected in systematic (but quite simple) ways and if suitable methods for analysis are then employed The contributors to this discussion were Prof R A Fisher (London), Prof J B S Haldane (London), Prof C Gini (Rome), Prof G Dahlberg (Upsala), Prof L T Hogben (Aberdeen)

Dr D P MURPHY (Philadelphia) described an extensive investigation on the children of mothers who had produced a *congenitally malformed child* The cases were obtained from death returns and represented in all probability, a good random sample of such children The chance that any subsequent child born to the mother would also be malformed was about one in eight, twelve times the expectation in the normal population The commonest malformations were hydrocephalus spina bifida and anencephalus In sibships containing more than one malformed child the type of malformation was usually, but by no means always, the same in the affected sibs Advanced maternal age was a factor of much importance

Dr BARBARA BURKS (Cold Spring Harbour) described genetic linkage between *hair colour* and *deficiency in the number of teeth* This has been demonstrated with a relatively high degree of probability and if finally confirmed will represent a notable landmark in the history of human genetics for it is the first demonstration of linkage in any pair of chromosomes other than the sex chromosomes

MENTAL DEFECT

Dr T A. MUNRO and Dr L S PENROSE (Colchester) have found that *phenylketonuria* (inability to break down phenyl alanine combined with low-grade mental deficiency) behaves as a simple recessive character There is some evidence, inconclusive as yet, that this gene may reside upon the same chromosome pair as the ABO blood groups Dr Munro, however, in answer to Professor Haldane (London) thought that it was premature to discuss this possibility further until more data are available Dr PENROSE stated that there was a genetic basis for *mongolism*, for a mongol child is ten times more likely to have a mongol relative than is a low-grade defective who is not a mongol Maternal age is well recognised as an important factor in the etiology of this condition, but it also plays a part in many others, including for example, pyloric stenosis

Dr J SANDERS (the Hague) described a family containing sixteen persons who suffered from *Pick's disease*[1], this is the largest group yet recorded The age at onset is about forty to fifty years, but it is possible that the application of mental tests may reveal the presence of the gene a considerable time before the disease becomes manifest The disease depends upon a dominant gene, so that diagnosis amongst the children of affected persons is of much practical importance if marriage is contemplated Up to the present the warning given by the mental-test results has been confirmed subsequently in three cases

Dr J A FRASER ROBERTS (Bristol) drew a distinction between *high- and low-grade defectives* The former are part of the normal curve of variability of intelligence and, in so far as heredity is involved, owe their mental state to the operation of multi factor inheritance Low grade mental deficiency may be of exogenous origin, but more often heredity is involved The genes which cause low grade deficiency are very numerous, each being responsible for a small proportion of cases only They are sometimes genes which affect other bodily systems also They include many genes which are expressed in a proportion of the bearers only In many of these last cases, the other necessary predisposing factors must be prenatal It is possible that such a gene makes its bearer unduly sensitive to minor variations which could not affect the development of the normal fœtus, trivial differences would then determine whether the central nervous system was affected or not in a particular bearer of the gene

Dr R J A BERRY (Bristol) described an analysis of the mental characteristics of the *relatives* of a large group of *mental defectives* The most striking finding was the notably higher proportion of affected children if a parent was also affected

MENTAL ILLNESS

Prof D K HENDERSON (Edinburgh) made a close analysis of eugenics in relation to *insanity* He considered that both negative and positive eugenics were involved in a constructive programme, but emphasised that improvements of environmental conditions must also be regarded as essential to such a programme It is easy to encourage too fatalistic a view of the hereditary determination of mental disease He would not be prepared to sacrifice the members of families containing manic depressive patients in order to reduce the incidence of the disease for such people, who might well exhibit slight degrees of abnormality, often possessed qualities which were of value to the

1 Pre-senile dementia *not* polycerositis

community. While not ruling out sterilisation as a useful procedure in a few selected cases, Professor Henderson criticised the findings of the departmental committee on sterilisation (1933), in that the indications suggested were so vague. He also criticised the German plan because it was so sweeping and might interfere with early treatment

Dr. F. J. KALLMANN (New York) stated that the inheritance of *schizophrenia* could be interpreted on the basis of a single recessive factor. This factor, however, was not always expressed and external circumstance may determine not only whether the bearer becomes affected or not, but also the features of the mental breakdown He did not consider that sterilisation could play anything but an insignificant part in eradicating this disease

BLOOD-GROUPS

In discussing *blood-groups*, Dr. V. FRIEDENREICH (Copenhagen) described the division of "A" into three varieties, distinguished by the strength of the reaction. A_1 is dominant to A_2 and A_3, and A_2 to A_3; A_3 is very rare, but the distinction between A_1 and A_2 is already employed medico-legally on the Continent, thereby increasing the proportion of cases in which false accusations of paternity can be disproved. An important piece of work by Dahr was mentioned. It is possible that persons of constitution AA may soon be distinguished from those of constitution AO This would still further increase the usefulness of the blood-groups in medico-legal work. Dr. G L TAYLOR (London) issued an impressive warning in regard to the danger of error in MN blood-grouping. The sera may easily contain unwanted antibodies and so give false positive results, or by over-exhaustion be rendered too weak and so yield false negative results. Further the sera may quickly lose their potency. Statistical examination of much published data obtained from all over the world clearly shows that many such records must contain a proportion of false results MN blood-grouping, especially of course in medico-legal work, is a procedure which should be left to serologists of experience.

Prof. R. RUGGLES GATES (London) discussed blood-groups from the anthropological point of view, and stated that while gene A probably arose in the common ancestors of anthropoid apes and man, gene B in all probability arose much later by parallel mutation in both stocks. Dr D. J. FINNEY (Harpenden) produced evidence which indicated that allergic disease may be linked genetically to the ABO blood-groups (the genes being situated upon the same chromosome pair). This however requires further confirmation.

TUMOURS

Dr. ALMA HOWARD and Dr. C L HUSKINS (Montreal) have found that the incidence of *mammary cancer* in various strains of *mice* is associated with the chiasma frequency, that is, with the frequency with which crossing over occurs between the chromosome pairs at certain stages Dr. MADGE T. MACKLIN (London, Canada) has analysed a series of human *twins* in which both members developed tumours. Some of the material was collected personally and some from the literature Out of thirty-four pairs of identical twins thirty-two showed the same kind of tumour occurring in the same organ, while two had tumours of different kinds Out of fifteen pairs of fraternal twins seven had the same type of tumour and eight dissimilar tumours In cases in which the age at onset was known, the mean difference in the case of the identical pairs was 1 3 years and in the fraternal pairs 12-1 years

ANIMAL EUTELEGENESIS

In the animal-breeding section a session was devoted to *artificial insemination*. This technique is now very widely used in agricultural practice throughout the world, and has attained a high degree of perfection in such animals as cattle and sheep Dr. J. ANDERSON (Naivasha, Kenya) stated that the artificial insemination of cattle was especially valuable in Kenya owing to the prevalence of genital disease transmitted by coitus About 12,000 cows per annum are now being inseminated The farmers themselves carry out the technique after receiving instruction In sheep the results are very nearly comparable to those obtained by natural methods Dr. T BONADONNA (Milan) stated that about a hundred centres were now at work in Italy and her colonies, some 80 per cent. of their activities being concerned with cattle. Other animals yield very successful results however; in sheep 80 to 90 per cent of pregnancies result; in mares 70 to 80 per cent, if more than one insemination is made during the heat period; in sows 90 per cent.; and in hens 90 to 100 per cent. Dr. R W PHILLIPS and associates (Idaho, U.S A) have experimented with long-range *transportation of rams' semen* and have obtained pregnancies after transportation for 2600 miles The longest interval between collection and successful insemination was 115 hours.

Dr. M. TEODOREANU (Bucharest) described particularly successful results in sheep, obtaining 96 5 per cent. of pregnancies, a figure equal to that of normal mating Dr J EDWARDS and Dr. A WALTON (Cambridge), who have been responsible for many advances in this field, described a careful investigation on factors controlling the fertilizing and storage properties of the semen of a group of bulls; further advances in technique may be anticipated in the near future.

Dr. M MANRESA and associates (Philippine Islands) have conducted experiments since 1930 to determine why *pure-bred cattle imported from countries* of temperate climate should prove unsuited to the Philippine Islands. Imported cattle had a much lower hæmoglobin content in the blood than native cattle. This is interpreted as a temperature effect, for variations in external temperature were associated with blood variations in the imported animals, though not in the native ones. The body temperature of the imported cattle was consistently higher than in the native cattle. It is concluded that high temperature and high relative humidity raise the body temperature of the imported animals with serious effects on the physico-chemical balance of the blood. Cross-bred progeny proved to be intermediate.

A feature of the congress was the wealth of demonstrations and exhibits. Particular interest was aroused by the demonstration on blood-grouping and taste-testing (for the ability to taste phenyl-thiocarbamide) arranged by the Galton laboratory of the University of London. Many visitors were blood-grouped and taste-tested, and at the end of the congress members were invited to observe an attempt to test the taste reactions to this substance of the anthropoid apes at the Edinburgh zoo

". . . 'There is no reason whatever to believe that the order of nature has any greater bias in favour of man than it had in favour of the ichthyosaur. . . . I perceive that now the universe is bored with him, is turning a hard face to him, and I see him being carried less and less intelligently and more and more rapidly . . . along the stream of fate to degradation, suffering and death'"—H G. WELLS, quoted in a review *Nature, Lond.*, Sept. 2, 1939, p. 397.

THE MOTORISED FIELD AMBULANCE

It is a well known principle of warfare that whereas both sides begin a war with the tactical ideas of the last war but one, the medical arrangements are based on the last war but five or six This cannot be said of the R.A.M.C in "Hitler's War," since the modern field ambulance has been entirely motorised, whereas the whole R.A.M.C at the beginning of the last war had at their disposal only seven motor ambulance cars [1] The questions now arise whether this mechanisation has gone far enough and whether it requires a radically altered organisation to make it fully effective Lieut.-Colonel Dowse [2] suggests that the modern field ambulance may not have kept pace with the enormous mobility conferred by mechanisation on the fighting arms He considers that, as now organised and equipped, it is not sufficiently mobile to carry out its primary duty of collecting and evacuating wounded, and that the present system of evacuation from the regimental aid post via the advanced dressing station to the main dressing station and thence by the motor ambulance column to the casualty clearing station is too cumbersome In the first place, 48 of the personnel of the field ambulance cannot be seated in the vehicles of the unit, and this must seriously handicap its mobility Secondly, Colonel Dowse maintains that the heavy ambulance is unsuitable for its purpose and that the number of motor ambulances in the forward area is inadequate

The essential change that Colonel Dowse would like to see made is the abolition of the main dressing station The surgeons say that 90 per cent of wounded should be in their hands for treatment as soon as possible after they become casualties irrespective (within limits) of the length of the journey What then is the purpose of the main dressing station, at which little operating can be—or is in fact—performed? Its abolition, together with its bulky equipment now carried by the headquarters company of the field ambulance, would allow all the personnel of the field ambulance to have a seat in motor vehicles The casualty clearing station, however, may be as much as 50 to 100 miles behind the forward troops, and therefore a forward operating centre of the C C S will be required, as was being developed at the end of the last war If cases are evacuated directly from the advanced dressing station to the casualty clearing station it is obvious that a great increase in the motor ambulances working in the forward areas will be necessary, and this would be obtained by absorbing most of the ambulances in the motor ambulance convoy into the "forward evacuating unit"—the name which Colonel Dowse suggests for his new organisation There are two duties of the field ambulances which would have to be transferred to non divisional medical units administered by the D M S or D D M S of army or corps respectively these are the tasks of establishing rest stations for sick and wounded who are likely to rejoin their units in a few days, and of gas centres for the special treatment of gas casualties Neither of these organisations needs to be mobile and the transfer from division to corps or army would be an advantage rather than otherwise

In view of its greater mobility the present cavalry field ambulance seems to be nearer the ideal than the infantry field ambulance but under the proposed organisation a single type of field ambulance will be suitable to work with all types of divisions, thus securing a desirable uniformity Colonel Dowse would prefer to see a proportion of the light two stretcher type of motor ambulance included in the forward evacuating unit, and he thinks that motor cycle stretcher carriers might be developed as in the French army The motor ambulances of the forward evacuating unit would consist of 20 heavy cars with H Q, and 5 heavy 10 light and 10 motor-cycle stretcher-carriers, or an additional 10 light cars, with each company, giving a total of 95 per division As regards personnel, Colonel Dowse supports the suggestion that bearer officers—i.e., promoted N C O s of the R.A.M.C—should be in charge of the evacuation of the forward areas, thus releasing qualified medical men for more essential services.

Thus Colonel Dowse envisages a divisional field ambulance or forward evacuating unit of a uniform and highly mobile type, whose duties would be confined to establishing advanced dressing stations, collecting the wounded and dispatching them to the C C S or its forward operating centre, to the rest station or to the gas centre As has been well said, a field ambulance is doing its duty best when it is empty

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

EDINBURGH IN WAR-TIME

One of the results of the medical A R P organisation in Scottish cities is the temporary disappearance of the hospital population In Edinburgh evacuation of the patients in the Royal Infirmary and the three municipal hospitals was carried out The seriously ill patients were accommodated in convalescent homes, public assistance institutions and so on, but, whereas before the war nearly 3000 beds were occupied by persons presumably requiring hospitalisation, only about 300 are now occupied The discharge of so many patients to their homes has thrown an enormous amount of work on the general practitioners at a time when their numbers are greatly reduced and many of them are hard at work on various A R P duties At the same time, the diagnostic services of the hospitals have stopped In the efforts which have been made to cater for civilian casualties, medical services for those who happen to fall ill during the initial stages of war have been rather overlooked Already however, the situation is coming under control In Edinburgh the public assistance institution is being rapidly converted into a general hospital and some of the beds in the Royal Infirmary are to be liberated from war purposes to supplement those which have so far been used for ordinary emergencies The infirmary will continue to hold empty 1000 beds in readiness for air raid casualties In radiological departments, the more time-consuming and laborious barium examinations are to be restarted shortly Needless to say, emergency radiology of fractures and so on, has not ceased

A R P IN THE UNIVERSITIES

The dramatic changes which have overtaken other public buildings in the last few days have not passed by the universities Apart from the sand bagging of the more important parts departmental staffs have been busy packing and placing in safe storage valuable apparatus specimens and other teaching and research material In Edinburgh continuous fire patrols of the university buildings are being organised, students

forming the personnel with members of the staff acting as leaders. The professorial staff has worked wonders in the rapid construction and equipment of first-aid posts and shelters In the medical school, ground-floor rooms in the anatomy department and the rooms of the students' reading room have been protected and well equipped with the necessary running water, sterilisers, dressings, stretchers, &c., while a canteen for the aid-post team is rapidly being finished The bowels of the earth are hollowed out into troglodyte shelters, into which, like threadworms in the appendix, everyone will crowd when the warbling sirens start

EAST FORTUNE SANATORIUM

Some time ago the Air Ministry announced their intention to acquire the ground about East Fortune Sanatorium for use as a landing-ground. The sanatorium authorities objected that the existence of the sanatorium and a landing-ground were incompatible, and that the institution, which accommodates 211 patients and serves the whole of the south-east of Scotland, would have to be given up. It has now been announced, however, through Mr. George Mathers, M.P. for the Linlithgow division, that the Ministry have decided not to proceed with their scheme.

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations. Each contributor is responsible for the section for a month, his name can be seen later in the half-yearly index

FROM D.P.M.

III

THE engineer deputed to reorganise my black curtains stood on the top of the ladder and delivered me a short address on Hitler. There was nothing strikingly new about it except that, in his opinion, Hitler was no leader. "I always say," he repeated, "that he's not a leader." I could think of no satisfactory reply to this, so he went on to tell me what his wife thought about the war; and here I found myself in my depth again, for his wife and I seem to share the same views

"I've blacked out our bathroom light," he said earnestly, "so that we get one little beam on the mirror for me to shave by. My missus said to me: 'Is that all the light we're going to get, then?' I said, 'Yes, my girl, that's all, till the war's over!' 'Cor,' she says, 'no light, no pictures, and nothing but music on the wireless. What do they think we are?'"

What indeed? No-one can deny that the atmosphere of Victorian piety in which this war is being conducted has grown thicker and thicker during the past week The niggardly crumbs of news doled out to us are no compensation for days which end at dusk, and nights spent in rooms muffled in black curtains and heated to the temperature of a moderate oven Even threatened air-raids are so well supervised that the wretch going through the streets is hurried down some hole in the ground by an air warden before he has a chance to explain his phobia (supposing he has one) of being buried alive All this paternal solicitude is very nice—but boring. Of course we should be grateful; we should be pleased to find ourselves safe, and to know that any news that might cause us a moment's uneasiness is being kept from us Perverse and foolish, however, we are as restive as children under the thumb of a too solicitous nanny, the sort who insists interminably upon a body-belt and a dry pair of socks.

Surely we could be treated more successfully as adults? What objection could there have been, for instance, to giving us at once the text of those leaflets dropped over Germany by our airmen? There was a splendid adventure, if ever there was one. Surely we deserved to hear that tale in full?

Is it just possible that this silence and organised gloom is part of a deep-laid scheme? Can it be that someone has at last realised that the way to make warfare universally and permanently unpopular is to make it boring? There is a strong strain of asceticism in mankind. Men and women will put up with unthinkable agony and grief if they believe it to be a good cause. On the other hand, no cause has yet been found to make boredom seem attractive. Or anyhow, to make it seem attractive to me and the engineer's wife, and I daresay there are plenty like us

* * *

This question of boredom is very interesting. Boredom must often have been responsible for wars, though no-one could complain that boredom led up to this one. Bored children squabble, bored nations, perhaps, go to war. In the Middle Ages, it has been suggested, boredom led to witch-hunts. Among villagers isolated from any sort of entertainment a suspected witch must have been a godsend. Among the border clans a chief at his wits' end to occupy a body of highly trained and quarrelsome clansmen must have been thankful to suggest a raid on someone else's cattle. In these situations the change was from a static to an active phase, a loosing of chained energy

But suppose we could reach a point where the reverse was the case, where the constructive activities of peace gave more outlet for our energy, skill and even our aggression, than the disciplines of war? Suppose war became the passive, boring phase, under which we fulminated to an uproarious and active peace? That would be a thing worth seeing. It would not necessarily mean the end of war, because human institutions are apt to be cyclic; there is a time for building up, we are told, and a time for breaking down But it would mean that wars were brief and unpopular—dull interruptions of our more violent deeds.

* * *

The emergency medical arrangements appear to have been carried out with great speed and accuracy; hospitals have been cleared for casualties and important units moved out of the danger zone. It is pleasant to know that some of the hospitals are evacuating their younger nurses to outlying institutions. London may seem dull at the moment, but there is no guarantee that it will remain so The seventeen- and eighteen-year-old nurses looking after London's mentally defective children are staying where they are with a very good grace.

One drawback to the emergency arrangements as they affect the civil population is beginning to show itself. A friend of mine in general practice tells me

that he sent a case of just operable cancer to all the hospitals in his region, but could get no treatment for her Many other doctors must have encountered similar difficulties The status of the civilian in wartime is always rather mysterious Presumably the army fights to protect the civilian, yet the civilian is always neglected in favour of the army He gets worse food, worse medical care and worse gas-masks It all seems very curious Either the civilian is worth protecting—in which case he is worth preserving, too, or else he is not worth protecting—in which case, why keep an army? I can't make it out

* * *

I suppose there are good reasons for training nurses to have blind faith in the doctor—except that I cannot suppose there is any really good reason for training anybody to have blind faith in anybody else Sometimes the trust of the nurse is stimulating and sometimes embarrassing, and *sometimes it makes one* wonder what goes on in the nurse's mind I have known a nurse refuse to admit she was looking after a case of pneumonia though she had been nursing the patient perfectly for a week, and had herself copied the word pneumonia on to the temperature chart in capital letters She said that she didn't like to own she knew it was pneumonia for fear the doctor would think she was making a diagnosis

I provoked one staggering exhibition of blind faith during the first air raid warning While I was waiting in one of the wards with a first aid squad the telephone rang, the voice of my senior officer came briskly over the wire "Fill the bath!" I turned to the nearest nurse—"Fill the bath," I said "Yes, doctor," she replied breathlessly, bolting like a rabbit into the bathroom A moment later her flushed and earnest *face appeared round the bathroom door* "Hot or cold, doctor?" If the incalculable creature chose this moment for a dip, hers not to question, I suppose she felt She put me in mind of Casabianca, whom I admire but cannot respect

* * *

A minor pleasure of war is to be found in filling sandbags Half the hospital turns out for this sport and prosecutes it with enthusiasm I did not realise until instructed by the gardener—who looks like Lloyd George but is less loquacious—that there is an art in filling a sandbag A full team consists of three one to delve and one to hold and one to tie the sacks They put me on to holding at first, that being the simplest job, but after a short trial Lloyd George shook his head and beckoned to one of our mental defectives to show me how it was done It seems you have to hold the back lip of the sack firmly, with your hands about eight inches apart and the canvas taut between them, the front lip of the sack then sags forward, leaving space for the introduction of the shovel It was some time before my performance satisfied the gardener After that they let me dig a little, and here again there are points to be observed, a sack must not be filled too full or it refuses to lie flat when banked among its fellows, and the shovel—our shovels are nearly as wide as the mouths of the sacks—have to be introduced tenderly or half the load trickles out and is wasted I discovered no special points about tying except that it blisters the left little finger

At first we filled the sacks from our meagre garden, with the result that some of them are now sprouting green blades and lending the wartime aspect of the hospital a hoary appearance already; later a fair portion of Clapham Common arrived on lorries and enthusiasm reached a high pitch I think the children felt that Bognor Regis had come to town, and greeted us on the morning round with "Doctor, can *I fill* sandbags? Can I fill sandbags, doctor?" Large and tireless parties gather on the imported dunes in every spare moment, using anything they can get, from seaside spades to ornamental fire-shovels, and the growing piles of sandbags lie round them looking like the malt sacks out of "This is the House that Jack Built" The padre who arrived hopefully to conduct a service was completely out of the running "You tell him he can go home and pray for us, sister," the patients said kindly to the worried messenger

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT 2, 1939

Notifications.—*The following cases of infectious* disease were notified during the week Smallpox, 0, scarlet fever, 1035, diphtheria, 756, enteric fever, 77 (53 "expected"), pneumonia (primary or influenzal), 301; puerperal pyrexia, 149, cerebrospinal fever, 18, poliomyelitis, 21, polio-encephalitis, 1, encephalitis lethargica, 1, dysentery, 26, ophthalmia neonatorum, 28 No case of cholera, plague or typhus fever was notified during the week

Deaths.—In 126 great towns, including London, there was no death from smallpox, 1 (0) from enteric fever, 2 (0) from measles, 3 (0) from scarlet fever, 5 (4) from whooping-cough, 14 (0) from diphtheria, 44 (6) from diarrhœa and enteritis under two years, and 8 (1) from influenza The figures in parentheses are those for London itself

Liverpool reported the only death from typhoid Fatal cases of diphtheria were scattered over 12 great towns, South Shields and West Bromwich each reporting 2 Liverpool had 9 deaths from diarrhœa, Birmingham 6, Nottingham 5

The number of stillbirths notified during the week was 231 (corresponding to a rate of 33 per 1000 total births), including 40 in London

The Lancet 100 Years Ago

From an article on small pox in Chelsea by Dr W B Marshall

I CARE not to mingle the question of money with that of the public health, and am not, therefore, solicitous to suggest any mode of remuneration for the authorised vaccinators, but I may add that the cost of coffins alone, for small pox patients, during the year ending April 30th, 1839, would, I am sure, have more than paid for the vaccination of every one who has been attacked with that disease during the same period, a clamour might, and, doubtless would, be raised against any law to that effect, upon its first introduction, but, like all senseless clamours, it would soon subside, and as the law came into operation, the benefits thereof would be better appreciated, and, of course, more cheerfully acceded to

---

"You shall always be told the truth in this war May be that at the front there is a serious reverse—that shall not be hidden from you. If listening to foreign radio stations is heavily punished, it is not because we fear them, but because it is dishonourable to listen to the dirty tirades of foreign countries"—Field Marshal Goering in a Berlin armament factory on Sept 9

"You can drop a bomb somewhere but you can broadcast the truth everywhere"—Sir WALFORD DAVIES quoting his taximan in a broadcast on Sunday evening, Sept 10

LETTERS TO THE EDITOR

RED CROSS AND ST. JOHN JOINT APPEAL

THE following letter, signed by the Duke of GLOUCESTER, Sir ARTHUR STANLEY and Lord SCARBROUGH, has been issued to the press by the Red Cross and St. John Emergency Committee

In the grave issues which now confront the British Empire, the British Red Cross Society, of which H.M the Queen is president, and the Order of St. John have decided to work together as they did in the last war with results which are still within the memory of the public With this object a Joint Emergency Committee has been set up, comprising an equal number of members of each body. Lord Cromer has consented to be the chairman of the committee with Major-General Sir John Kennedy as vice-chairman.

In this war, which is so entirely different from any that has preceded it, it is impossible to foresee exactly where relief for the sick and wounded will be most needed, or in what form But it is certain that there will be vast suffering and distress and that the relief of the sick and wounded of His Majesty's forces, and of the civilian population, will call for much voluntary effort and financial support Considerable voluntary help has already been secured but it remains to find the money necessary to pursue the work. In the great war, and indeed at all times, appeals made by the British Red Cross Society and the Order of St John received the most generous response, showing that the heart of the Empire is with those who are risking their lives in support of the rights and liberties, not only of the peoples of the British Commonwealth of Nations, but of the whole civilised world

We earnestly ask you to help the Joint Committee in the great work that lies before them. A fund is being opened in the name of the joint bodies Donations should be sent to The Hon. Sir William H Goschen, K B E , hon treasurer, Red Cross and St John Fund, at Messrs. Coutts & Co , 1, Park Lane, London, W.1

DIPTEROUS LARVÆ AND WOUND TREATMENT

SIR,—When troops wounded in battle have been lying out on the ground, unattended for some time, their wounds very commonly become infested with larvæ of certain kinds of flies In the war of 1914–18 W S Baer [1] noticed specially that when the wounds had acquired about their maximum maggot population they did not exhibit dangerous after-effects On the other hand, men whose wounds had received prompt early treatment often developed infection It was found that the presence of these larvæ was especially beneficial in cases of osteomyelitis. It was discovered that the larvæ were eating the necrotic tissue which was supporting the main bacterial infection and, at the same time, these larvæ were inhibiting further bacterial growth Stewart [2] claimed that the scavenging larvæ play an important part in clearing the necrotic tissue, but that calcium carbonate, which is constantly excreted by the larvæ, is also important in alkalising the medium (the wound), in which the bacteria live, and of increasing phagocytic activity The larvæ used in the earlier treatment of osteomyelitis belonged chiefly to the species *Lucilia sericata* (Meigen), *L cæsar* (L) and *Phormia regina* (Meigen) Stewart [3] showed, however, that due precautions must be taken and a proper knowledge of the biology of these larvæ is essential. Some species will feed on both necrotic and normal tissue and are potentially dangerous to the latter.

Much study has been devoted to the technique of rearing dipterous larvæ under aseptic conditions, and also of retarding their normal development, until they were actually needed for implantation within wounds Sterilisation of the eggs in a 5 per cent solution of formaldehyde, mixed with a 1 per cent solution of sodium hydroxide, for five minutes has been found satisfactory by Robinson [4]; he gives full details of this process, and that of the subsequent rearing of the larvæ Livingston and Prince [5] were successful in eliminating the inconvenience and unpleasantness associated with the actual "maggot therapy" by using a sterile extract of the creatures themselves Robinson [6] claimed that the blow-fly larvæ contain allantoin in their excretion and that the rapid healing of wounds as the result of "maggot therapy" is due in the main to this agent He did not claim, however, that it could be entirely substituted for the application of the living larvæ Robinson carried his investigations further and found that a watery solution of allantoin provides the necessary healing agent, without the presence of dipterous larvæ at all In 1935 allantoin was a rare chemical in the laboratory but it soon became to be made synthetically. Robinson also pointed out that a part of the allantoin molecule can be split off by hydrolysis to form urea. Further work led to the discovery that a 2 per cent watery solution of urea has the equal healing properties of allantoin or of the fly larvæ themselves It has the further advantage of being much cheaper than allantoin Not only osteomyelitis, but many other kinds of non-healing wounds, have been treated in the manner just described—including gas-gangrene, heat burns, X-ray burns, and varicose and diabetic ulcers So far as I am aware Paramorow in 1934 [7] was the first to use dipterous larvæ in the treatment of gas-gangrene He applied maggots of the house-fly, *Musca domestica*, since calliphora larvæ were prone to devour healthy as well as necrotic tissue He states that he cured three cases of gas-gangrene when amputation appeared inevitable, and that the healing process began 48 hours after the treatment began.

In this brief summary I have stated the present position of the subject in so far as it is known to me. It is desirable, at the present early stage in the world calamity that we are facing, that the foregoing information should be made as widely known as possible There is no doubt that further research into the technique of this method is urgently required Also, I believe that it is correct to say that this method of wound treatment has been more widely explored in the U.S.A than in England The literature on the subject is already extensive and I have only mentioned a few of the chief writings here.

I am, Sir, yours faithfully,

A. D. IMMS, F.R.S.

NEUROSIS OR PSYCHOSIS?

SIR,—Far be it from me at the present time to embark upon, or to encourage, controversy on this endless theme As, however, you referred to my writings and views in the leading article from which this correspondence arose, I may perhaps be allowed to make two brief statements on the matter

The first is that if the suggestion that an anxiety neurosis and a melancholic depression have anything in common with each other in either ætiology, symptoms, course or treatment, is to be accepted or even to pass unchallenged, I for one should feel that our terminology and psychopathology were futile from beginning to end, and should withdraw in despair from any further attempt at argument or discussion I fancy that I should do so in fairly good company The second is that it is unfortunately possible that we may all before very long have ample opportunity to observe the greatness of the gulf that separates neurosis from psychosis I pointed out several years ago that no better help to the differential diagnosis exists than an air raid No one who has experienced an air raid in the company of a number of both neurotics and psychotics is likely ever again to be in doubt as to whether the difference between the two is "quantitative" or "qualitative" I need not say that I share the universal hope that we shall be spared this acid test, and I trust that Dr Symonds and Dr Gillespie may be able to compose their differences without having to wait for it Of course, any observant mental hospital physician who has noted the reaction of the patients in his "convalescent" wards to a thunderstorm could say a good deal about the profound difference between neurosis and psychosis, but his evidence would, I fear, be regarded as tainted

Is it so very difficult to admit that even a psychosis must have a beginning, and that it may very often be undiagnosable or misdiagnosed at first, even by an experienced man? I cannot think that anything is gained—and the reputation of our specialty is certainly damaged—by confidently labelling an early, doubtful or undiagnosable psychosis as a neurosis, and endeavouring to have it both ways by asserting that the one may turn into the other

I am, Sir, yours faithfully,

HENRY YELLOWLEES

Harley street, W 1, Sept 11

"DORMANT" LEAD POISONING

SIR,—I hope it may be my mistake, but I seem to detect some hint of superbity in Dr R E Lane's comments on the above subject His experience of industrial lead poisoning is not in question, his knowledge of lead poisoning in war conditions has yet to emerge If he will read my letter again he will see that I have not ascribed symptoms to lead that had been absorbed many years previously' These cases to which I referred had been absorbing lead up to the time of their joining the army perhaps two or three years before I saw them, sometimes less This is not many years" A considerable incidence of lead poisoning, diagnosed on clinical and haimato'ogical grounds, was apparent for the first time after joining up I should be more strictly accurate if I said that a considerable incidence of *acute* symptoms was seen, many of the older patients had suffered from constipation and other symptoms, possibly due to lead for long periods I claim to have made a clinical and haematological observation and to have drawn from it a not unreasonable deduction as to one aspect of lead intoxication My case records perished long ago so that I cannot give precise details

When Dr Lane has had a similar experience he will be in a better position to plead for "a more critical attitude" and to condemn 'a seemingly plausible explanation" as if his middle name was Tarquin I trust he will not mislike the comparison

I am, Sir, yours faithfully,

GORDON WARD.

Sevenoaks, Kent, Sept 9

A WAR-TIME PHARMACOPŒIA?

SIR,—In the present circumstances it is imperative to study forthwith means of preserving supplies of certain substances which, although widely prescribed, have little or no therapeutic value Syrups, used solely as flavouring agents, edible oils and fats as ointment bases, alcohol in many tinctures, are instances of valuable substances which could be replaced. Belladonna pulverata, digitalis pulverata, and ergota preparata could be given in tablet form instead of the corresponding tinctures and extracts This would mean the saving of alcohol and in addition, owing to the reduction in bulk, storage and transport problems would be simplified *Now* is the time to devise a war-emergency pharmacopœia for the whole country A small committee of representatives of the medical and pharmaceutical professions would have little difficulty in compiling a national formulary Such a pharmacopœia is an urgent necessity

I am, Sir, yours faithfully,

H DAVIS,
Chief Pharmacist

University College Hospital, London, W C 1, Sept 7

EXPOSURE OF THE FACIAL NERVE

SIR,—Mr Morris's article on the surgical treatment of facial paralysis (*Lancet*, 1939, Sept 2, p 558) prompts me to record an easy method of approach to the facial nerve trunk This I devised some forty years ago I used to chisel off the tip of the mastoid process, with the insertion of the sterno mastoid The muscle and mastoid are turned downwards, thus exposing the nerve as it emerges from the stylomastoid foramen It can then be followed with ease in either direction I used this exposure first in cases of catarrhal palsy, which I now generally treat with diathermy

I am, Sir, yours faithfully,

W KENT HUGHES

Melbourne, July 12

FOR TRACHEOTOMY CASES

SIR,—I feel that arrangements should be made for patients who have to wear tracheotomy tubes to be given some protection against gas Evacuation or if this is impossible their admission to a gas proofed hospital ward would seem the most convenient way of dealing with the problem

I am, Sir, yours faithfully,

W A MILL.

Harley street, W 1, Sept. 11

UNIVERSITY OF CAMBRIDGE.—We understand from Dr Russell Reynolds that he has not resigned his examinership for the diploma in medical radiology, as stated in the *Cambridge University Reporter* and in our issue of Sept 2 Dr Keeley is taking his place for the October examination only

PARLIAMENTARY INTELLIGENCE

ON THE FLOOR OF THE HOUSE

By MEDICUS, M.P.

FROM the day on which the Emergency Powers (Defence) Bill was passed through all its stages, including of course the royal assent, on Aug. 24 until to-day Parliament, the machinery of the defence services, the civil services, the industrial and business life of the nation and every other aspect of our lives have gone through a series of rapid changes. It is not only that Great Britain, the Dominions, India and the Colonial Empire have gone to war, it is that we have gone to war in an organised and deliberate way more like the stage of growth in some living creature than the work of millions of brains and millions of hands. The nation has been equipping itself for the possible danger of war in an intensive campaign ever since last year—and our preparations before that were on a great scale, but during that period the mind of Parliament and the nation has also been changing and equipping itself as perhaps never before in history.

When the final day had all but come and Parliament met on Friday and Saturday Sept. 1 and 2 there was not only organic change visible, there was a passion for righteousness visible as a consuming fire. When at 7.44 p.m. on Saturday Sept. 2 the Prime Minister rose to make his speech on the situation between Germany and Poland members were tense with expectation, for we had been sitting discussing important bills—but discussing while waiting for the all-important announcement expected. And when the Prime Minister's statement came it revealed delaying tactics by the Germans, failure to reply to the British demand that hostilities between Poland and Germany should cease, and a proposal from Italy for an immediate conference of Great Britain, France, Poland, Germany and Italy. It also contained a statement that Great Britain would not agree to a conference while Poland continued to be invaded, and that Great Britain did not recognise the German pretence to have annexed Dantzig to the German Reich But it did not contain a declaration breaking off relations with Germany, and the passion in the hearts of M.P.'s of all parties swept into a tumultuous expression of anger. When Mr. Greenwood, leader of the Opposition, rose he was greeted, from the Tory benches, from the mouths of ex-cabinet ministers, from the Labour benches and from the Liberal benches with a roar asking for a lead for Britain. "Speak for England" called out two former Tory cabinet ministers; "Give a lead" called other members Words could barely be heard in the roar of many voices expressing many feelings, but all united in the passionate desire to show unmistakably and definitely where Great Britain stood.

In that flame of a passion for righteousness the new Britain was born The trend of events in Europe over a year had been paralleled by changes in the structure of our country like those in some vast chrysalis Iron and steel and concrete defence taking the place of the softer structures of peace; large, swift acting and complex nervous mechanisms of central and departmental control superseding the more leisurely ways of normal days; new organs of offence in the air, on the sea and on land growing in power monthly, weekly, almost daily And above all a change in spirit. Hatred of war among all classes, full realisation of horrors of war among all classes, and yet a determination, deep founded, expressed sometimes with difficulty but practically everywhere · "We've got to have done with this Hitler business." Then Parliament met on Sunday. The actual words of the Prime Minister in the House of Commons on Sunday morning were to announce the fact that during the night an ultimatum had been sent to Germany demanding a reply by 11 a.m., that no reply had been received and that we were in consequence, when the statement was made, already at war. All members had known this before from the air-raid warning which wailed over London soon after 11 a.m. But the actual words gave a feeling of profound relief The change from the old order to the new was made. Britain was at war—not against Germany, but against Hitlerism.

* * *

Since Sept. 1 the work of Parliament has gone on regularly and in the new way—acts being passed by the dozen, often going through all their stages in one session, in order to give Government the powers it needs Opposition and Government, not unity in one government but unity in a new form of association in which Opposition members act as critical advisers to the Government. The rights of discussion and free speech maintained, the freedom of the democracy carefully safeguarded for the future, the right of parliamentary criticism emphasised

Already there have been two interesting medical results of that. On the Personal Injuries (Emergency Provisions) Bill introduced by Sir Walter Womersley, the Minister of Pensions, constructive criticism elicited that the Government were paying especial attention to the cases of head injuries and the "shell shock" class of case On the main conscription measure, as the result of criticism, the Minister of War gave a definite undertaking that he would not send youths under 20 overseas unless the emergency demanded it and unless he had previously (if possible) consulted the House and given it the opportunity of criticism. The objection to sending boys of 18–20 overseas was the medical one that they were not hard enough for this work and that it was a waste of man power, because a a misuse of man power, to do it

The work of Parliament is to go on. The House of Commons will meet usually each week and it will keep all vital matters under review. But it is a House with a new spirit There is no division in the feeling that the nation has entered on a righteous war against Hitlerism and that it must be pursued until the Nazi government and all it stands for is swept out of existence And after the War? Already men and women are thinking in terms very different from those of 1914–18. There are no heroics about this war and no heroics in Parliament.

The future must be remade, and remade on a basis of realistic and objective observation Medical science and the other sciences will play a greater part in the future than they have in the past. The problem of adequate nutrition, for example, must cease to be a problem for all classes of the population.

From now onwards the mind of Britain is directed to the war. The great machine of offence and defence created by Democracy moves on; it will go on relentlessly and irresistibly, but it is not motived by hatred of any people, it is inspired by the love of freedom.

MEDICAL NEWS

Drug Fluctuations

The price of crude iodine has advanced by 30 per cent, this will affect quotations for tincture of iodine, potassium iodide, sodium iodide and all iodine preparations The price of quicksilver has also been raised by some 30 per cent, which will justify a rise in the cost of calomel corrosive sublimate and all preparations of mercury The cost of bismuth metal is higher, and makers of bismuth carbonate and other bismuth compounds have advanced their quotations by about 10 per cent There has been a substantial increase in the cost of quinine sulphate and other quinine salts, prices are based on the Dutch florin which, like the American dollar, has moved against sterling, up to the present the rise in the price of quinine sulphate is about 20 per cent Caffeine and theobromine are dearer to a similar extent, the prices of both being based on Dutch currency To a smaller degree the prices of methyl salicylate, phenazone benzoic acid, sodium benzoate, methyl salicylate and menthol have also been advanced Practically all drugs of vegetable origin are dearer to a varying extent, in due course the higher prices will be reflected in quotations for tinctures, extracts and other galenical preparations, and also alkaloids In the case of vegetable drugs dealers who hold supplies are rationing their clients where it is necessary or advisable to do so, with a view to conserving stocks until these can be replenished The same applies to medicinal essential oils It should be mentioned that an addition of about 5 per cent may be made to the price of all drugs in order to cover the war risk insurance of stock which is now compulsory

Surgical Instruments Wanted

The regional commissioner for Scotland announces that as a result of the large hospital extensions, heavy demands are being made on manufacturers of surgical instruments and appliances It would be a public service if private institutions and nursing-homes, medical men and firms, possessing surplus stocks, large or small of the following would communicate with the Secretary, Department of Health for Scotland, 121A, Princes Street, Edinburgh Artery forceps and other commonly used surgical forceps, surgical clamps, towel clips, hooks, retractors; surgical knives, osteotomes, hypodermic syringes, bedpans, catgut, irrigator stands, sterilising packs of any type, fish kettles, accurate lotion thermometers for use in X ray departments, and any other of the more common surgical instruments and apparatus The department of health for Scotland is prepared either to purchase or to take on loan any of the articles mentioned provided, of course, that they are considered suitable

Norwegian Tuberculosis Conference

The Nordisk Tuberkulose Laegeforening held a conference in Trondheim from June 23 to 25 at which Denmark, Finland, Norway and Sweden were represented by their leading specialists The two main subjects discussed were the relationship between the primary infection and destructive pulmonary tuberculosis and the indications for thoracoplastic operations Speaking on tuberculin tests one delegate mentioned that he has found that by repeating tests frequently on the same subjects it is not very rare to find definitely positive reactions giving place to negative reactions It was generally agreed that considerable, if not absolute protection can be conferred against tuberculosis by inoculating tuberculin negative reactors with B C G, and approval was expressed of the principle of vaccinating with B C G those who after the age of 12 are still tuberculin negative even if they are not living in tuberculous surroundings One of the most important communications was made by Dr Andersson of Gothenburg who on a follow up study of about 1000 children inoculated with B C G between 1927 and 1937 showed that not one of them had developed tuberculosis On the invitation of Swedish tuberculosis specialists, it is hoped to hold the next conference in Sweden in 1941

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty held on Sept 4, with Dr John Henderson, the president, in the chair, Dr James Cuthbert (Kelso) was admitted to the fellowship

Commissions in the R A.M C and the A D C

Doctors who wish to place their services with the Army should register their names with the Central Emergency Committee of the British Medical Association, and should not apply direct to the War Office Qualified dental surgeons wishing to obtain commissions in the Army Dental Corps should communicate with the Central Dental War Committee, 13, Hill Street, London, W I, or, if resident in Scotland, with the Scottish Central Dental War Committee, care of the Department of Health for Scotland, Edinburgh, 2

Emergency Medical Service

In the House of Commons on Sept 7 the Prime Minister said that over 200,000 hospital beds were now ready for air raid casualties, 56 500 of these were in the London region, 15,500 being inside the county and 41,000 outside The beds in any region would of course be available to meet the needs of any other hard pressed area Over 11,000 trained nurses, 4000 assistant nurses and 50,000 auxiliary nurses had joined the Civil Nursing Reserve for service in hospitals or first aid posts but more trained nurses and auxiliaries were needed, especially women who could give whole time service in any part of the country. Nearly 2500 doctors had accepted enrolment in the emergency medical service and acceptances were being received daily

Relief for Evacuated Persons

The Unemployment Assistance Board has been empowered to pay allowances to people in distress arising out of the war, even though they are not within the ordinary unemployment assistance scheme Persons applying for relief must be over 16 and must provo evacuation from home under a Government plan and to be in need as a result, or that he or she, or the person on whom normally dependent for support, has been deprived entirely or to a substantial extent of normal means of livelihood by the war Allowances will be calculated on the same scale as the ordinary unemployment assistance allowances and will be subject to generally similar provisions regarding the treatment of resources

Hospitals in Northern Ireland

A general survey of the hospitals in Northern Ireland has been made and information has been collected of the number of existing beds, the number of additional beds which could be accommodated in existing premises, and as to the sanitary arrangements and equipment The Minister of Home Affairs has appointed Dr I M B Allen to be Hospital Officer, and he has drawn up a memorandum in which the organisation of the Emergency Hospital Service is explained

The hospitals have been classified into four groups Group 1 includes the hospitals in Belfast which will receive general and special casualties, group 2 the hospitals outside Belfast which be in areas in which casualties may also be expected to occur, and which will be expected to receive such casualties and also casualties from the outlying parts of Belfast

The hospitals in group 3 are those situated outside the area in which casualties may be expected to occur and these will receive only unexpected casualties from their own neighbourhood but will be expected to maintain medical services for ordinary patients who might otherwise go to hospitals in groups 1 or 2, and to receive such patients and convalescent casualties from hospitals in groups 1 and 2

Group 4 is made up of hospitals in Belfast with specially limited equipment or accommodation upon which no demand will be made except in exceptional need.

EMERGENCY NOTICES

The examining board in England of the Royal Colleges of Physicians and Surgeons announces that (1) The final L.R.C.P. and M.R.C.S. examinations, advertised to begin on Sept. 27, will, it is anticipated, begin on that date. Certain relaxations in the regulations for admission have been made. (2) The first examination in anatomy, physiology, materia medica and pharmacology, advertised to begin on Sept. 20, will, it is expected, begin on or about Oct. 18, and the date of entry has been extended to Tuesday, Sept. 26. In view of certain relaxations which have been made in the regulations for admission to this examination, candidates who have not already entered are advised to write at once to the secretary of the examining board. (3) The pre-medical examination in chemistry, physics and biology, advertised to begin on Sept. 18, will, it is expected, begin on or about Oct. 23, and the date of entry for the examination has been extended to Monday, Oct. 2. (4) Certain modifications in the conduct of these examinations are necessary, and candidates must be prepared to be examined outside London. (5) The offices of the secretary of the Examining Board in England, at the Examination Hall, Queen Square, London, W.C.1, will be open from 9 A.M. to 4 P.M. daily from Monday to Friday, and will be closed on Saturdays.

The temporary address of the central administrative offices of the University of London is Royal Holloway College, Englefield Green, Surrey.

The university session at Manchester will probably begin as arranged on Oct. 5. Students from St. Mary's Hospital medical school, London, will be transferred to Manchester to continue their studies there.

Full Term will probably begin at Oxford as arranged on Oct. 15.

University College, London, has moved to Aberystwyth, and communications should be sent to it there, care of University College of Wales.

The work of the Glasgow Post-Graduate Medical Association has been suspended indefinitely.

The central offices of the Queen's Institute of District Nursing are being moved to the Hermitage, East Grinstead. (Tel. East Grinstead 129.)

The offices of the *British Dental Journal* have been temporarily removed to 5, Westleigh Road, Barton Seagrave, Kettering. All the other activities of the British Dental Association will for the present be carried on at 13, Hill Street, W.1.

The Royal Sanitary Institute has cancelled its classes of instruction and sessional meetings until further notice. The work of the institute will continue to be carried out at 90, Buckingham Palace Road, Westminster, London, S.W.1, and should this become impossible at "Darroch," Harrow Road West, Dorking, Surrey. (Tel. Dorking 2877.)

The public and private business meetings of the Association of Industrial Medical Officers have been cancelled until further notice. Communications regarding the association should be addressed to the hon. secretary, Dr. D. Stewart, 50, Frederick Road, Edgbaston, Birmingham, 16.

The office of the Ross Institute of Tropical Hygiene has been moved to 29, Inglis Road, Ealing, London, W.5. (Tel. Acorn 1534.)

The annual meeting of the International Society of Medical Hydrology, announced to take place in Italy from Oct. 14 to 19, has been indefinitely postponed. The office of the society at 22, Bedford Place is being kept on for the present, but the October number of its *Archives of Medical Hydrology* will not be published, and general office activities are being reduced to a minimum.

The annual meeting of the British branch of the International League against Epilepsy has been abandoned.

It has been arranged by the sector office that the Central London Throat, Nose and Ear Hospital in Gray's Inn Road shall continue its normal work, as the other throat, nose and ear hospitals are closed.

The National Hospital for Diseases of the Heart, Westmoreland Street, W.1, has been closed, but has reopened for the reception of inpatients at Maids Moreton Hall, Buckingham. Doctors requiring information should apply to the R.M.O. at that address. (Tel. Buckingham 2235.)

The St. Thomas's Hospital old students' dinner, arranged for Oct. 6 at the Dorchester Hotel, has been cancelled.

Until further notice the address of the Medical Women's Federation will be 73, Bourne Way, Hayes, Bromley, Kent. (Tel. Hurstway 1904.)

The London offices of the Royal Medical Benevolent Fund have been closed and the more important registers and records have been moved to Wormingford Grove, Wormingford, Essex. For the present it is impossible to consider giving financial help to any new applicants.

The emergency headquarters of the Pharmaceutical Society are at Birdgrove House, Mayfield, near Ashbourne, Derbyshire. The offices at 17, Bloomsbury Square, London, W.C.1, will remain open for the present to deal with urgent business. For the time being the *Pharmaceutical Journal* will be published at 23, Bloomsbury Square. The college of the society is housed at University College, Cardiff, and the various courses of instruction will be distributed between the University College of South Wales, the Technical College and the Welsh National School of Medicine. The society's pharmacological laboratories have been transferred to Reading. The September examinations have been postponed because a number of candidates have been called up for service.

The Royal Cancer Hospital, Fulham Road, are now able to receive and treat a limited number of cases of malignant disease. The outpatient and X-ray therapy departments are working as usual.

Royal Appointments

Sir Thomas Dunhill has been promoted sergeant-surgeon to the King and Colonel Benjamin Biggar, F.R.C.S., has been appointed hon. surgeon to the King in succession to Colonel J. M. Weddell, who has retired. Major-General Francis Casement, M.B., has been appointed hon. surgeon to the King in succession to Major-General H. M. J. Perry, who retires on Sept. 26. Mr. G. Gordon Bruce, F.R.C.S., is to be a surgeon to His Majesty in Scotland.

Arrangements at Ventnor

Realising that the war has thrown all efforts to treat tuberculosis into confusion, that many cases of tuberculosis have been discharged from sanatoria half-way through their treatment, that many others will be denied the benefits of treatment, and in addition that there will be many cases left in unsuitable, ill-ventilated, sandbagged houses who will be a danger to others, Dr. Fairley, the county medical officer of the Isle of Wight, has arranged with the Ministry of Health to take over two *holiday camps* to be run in conjunction with the Royal National Hospital for Consumption, Ventnor. It will accordingly be possible to deal with cases requiring treatment in bed in the hospital and with all ambulant cases in the holiday camps. It is hoped that ultimately there will be approximately 750 beds available. The camps will have a capacity of about 250 men and 100 women accommodated in 2- or 3-bed chalets. They will be reserved for *ambulant* cases of pulmonary tuberculosis, and patients will be expected to make their own beds, keep their chalets tidy, and generally assist in the work as far as their health allows. There will be a resident matron in each camp and any patient suffering from a relapse or any condition requiring treatment in bed will be transferred to the hospital.

WAR PREPARATIONS IN IRELAND

Our Dublin correspondent writes Although Ireland is not—for the present at any rate—a belligerent country, neither the authorities nor the public are neglecting the possibility of its becoming so, and preparations for emergencies arising out of the war are being rapidly pushed forward The hospitals, as well as private householders have been urged to render their buildings as secure as may be against the dangers of air raids It hardly needs emphasising that in the event of a raid reaching Dublin—whether by accident or design—the danger of fire from incendiary bombs would be very great, and there is no building in which a fire is so hard to combat as a hospital It is, therefore, incumbent on the authorities of the hospitals to render the buildings as safe as may be, and it will probably be necessary in the first instance to arrange for the vacating of all top storeys

The provision of hospital accommodation for possible casualties has also to be studied The Irish sweepstakes have not yet succeeded in adding appreciably to the number of general hospital beds in Dublin or Cork, and there is a definite shortage of hospital beds at present To find accommodation in an emergency for some hundreds of additional hospital cases would be, in these present conditions, beyond the power of the Dublin hospitals, but it is understood that the question is being carefully considered

The St John Ambulance Brigade in Ireland, to which the country owes much both in peace and war in the past, has been very active both in training its personnel in air-raid precautions and in increasing the number of its members For the past twelve months classes in first aid and in A R P have been held regularly, and have been attended by several hundreds of men and women On Sept 6, a public meeting to attract recruits for a special reserve of the brigade was held at the premises of the Royal Dublin Society, and the attendance was such as to surprise and even to embarrass the organisers Over 2000 persons attended, and over 1400 fresh volunteers signed forms of application for various classes of voluntary service

The Irish Red Cross Society—powers for the establishment of which was given by legislation last spring—has come into being The Government nominated the first council, but in future the society is to be both self supporting and self managed The President of Ireland (Dr Douglas Hyde) accepted appointment as president of the society and he nominated as chairman of the executive committee Mr Charles Mac Auley F R C S The council is thoroughly representative and contains many members who have a long experience of work in societies with similar general service Among these members are the commissioner of the St John Ambulance Brigade in Ireland (Sir John Lumsden) and members of his district staff Cordial cooperation between the brigade and the society is certain to be secured

Appointments

BACON, EDWARD M B Lond D O M S, hon assistant ophthalmic surgeon to the Royal Hospital Southampton

BECK, ANDREW, M D Glasg D P H, assistant county medical officer of health for Devon and district medical officer of health for the borough of Clifton Dartmouth Hardness and urban districts of Brixham and Paignton

HUGHES, JOHN B Chir Camb F R C S resident surgical officer at the Montagu Hospital Mexborough

JONES, IDRIS G M D Lond., M R C P hon assistant physician to the Cardiff Royal Infirmary

JONES, R M R C S D P H medical superintendent at the Bridge Home Witham (branch of the Royal Eastern Counties Institution)

MACKAY, J D M B Aberd, D P H temporary assistant medical officer of health for Barrow in Furness

MACKINNON, N A M, M B Edin., D P H, deputy medical officer of health for Bury

MELDRUM, C B M B St And junior assistant medical officer at the Argyll and Bute District Mental Hospital Lochgilphead

MILLS, W G Q M B Camb, F R C S resident surgical officer at the Radcliffe Infirmary Oxford

NEILSON, E E, B.M Oxf F R C S, surgeon to the London Hospital

REID, J M B Edin F R C S E resident surgical officer at Cumberland Infirmary Carlisle

SUTHERLAND, MARIE S M B Aberd D P H, deputy medical officer of health and deputy school medical officer for Accrington

WILSON, G F, L M S S A temporary medical officer for casualty services for Epping and Ongar

WOLFENDEN, D H L, M D Lond D P H, assistant medical officer of health for Rotherham

Births, Marriages and Deaths

BIRTHS

DOWLER.—On Sept 8 wife of Dr H G Dowler, of Church down, Gloucester—a daughter

HATTON.—On Sept 5, the wife of Dr P L S Hatton—a daughter

JAMESON.—On Aug 29 at Blackheath the wife of Captain James Jameson R.A.M.C.—a daughter

O'MEARA.—On Sept 6 at Catterick Camp Yorks, the wife of Major F W O'Meara R.A.M.C.—a son

PESKETT.—On Sept 4, the wife of Dr G L Peskett, of Newport Isle of Wight—a son

SNOWMAN.—On Sept 11, the wife of Dr L V Snowman of Finchley Road London, a daughter

TURTLE.—On Sept 7, at Bournemouth, the wife of Dr Peter de Boe Turtle—a daughter

MARRIAGES

BULLINGER—LLOYD.—On Sept 10 at Evesham, Owen David Bullinger, M B to Mary Lloyd

CORBIN—BUNTING.—On Sept 4, at Worcester, John Ogilvie Corbin, M B to Elisabeth Mary Bunting M B

CROOK—DYSON.—On Sept 4, at Crookham Parish Church, Aldershot Lieutenant Anthony Crook, M R C S, R A M C, to Roberta May Brabazon Dyson

GREES—UNWIN.—On Sept 4 at Wokingham, Theodor Anton Green F R C S, to Susan Melinda Unthank

HARRISON—HOWES.—On Sept 3, John Ormerod Harrison, F R C S to Mary Bowen

HEISER—NOBLE.—On Sept 2, at Eastbourne, Ronald Brodie Heiser, M B, to Muriel Margaret Noble

LEARY—MCKINLAY.—On Sept 7, at St Columba's, Pont Street Lieut. Colonel Thomas Garnet Stirling Leary, A.M.C., to Annie Eileen McKinlay

LOWN—SANKLIN.—On Sept 2, at Epsom Dr J F Lown to Miss F F Sanklin

MCINTYRE—SHEPPARD.—On Sept 9 at St George's Hanover Square Ivan Gordon McIntyre M B to Anne Lowson Sheed

MCLACHLAN—CANNING.—On Sept. 7, at All Souls, Langham Place Angus Fitch William McLachlan, M B, to Helen M Canning

OLLIVENSHAW—TIMPSON.—On Sept 6 at Didsbury Parish Church Captain Robert George Watson Ollivenshaw B M, R.A.M.C (T) to Kathleen Mary Timpson

PATON—REID.—On Sept 8 at Edinburgh Parish Church Henry Oldham Paton M B to Margaret Elizabeth Reid

PRITE—MACKENZIE.—On Sept 9 at Amberley Frank Richard Pepper B.M. to Patricia Mackenzie

ROSS—MACCOLL.—On Sept 4 at St Marylebone Parish Church Dr T A Ross to Mrs E C Macoll

SHAW—MACCOLL.—On Sept 6, at Beaconsfield Elizabeth Church Colin Carter Shaw M R C.S, to Daphne Vera MacColl

SLOAN—HENRY.—On Sept 8, at Guildford David Robert Sloan M B, to Alice Joanne Henry

STEWART—DICKINSON.—On Sept 4 at Sunbury-on Thames Richard Arthur Stewart M C., M B, to Alice Mary Dickinson

WARNOCK—THOMPSON.—On Sept 6 at Totland, John William Brodie Warnock M R C S to Margaret Thompson

WILLIAMS—HORTON.—On Sept 7 at St Marylebone Parish Church Leslie Charles Williams, M C., to Kathleen Miriam Horton M R C S

DEATHS

BLISSETT.—On Sept 6 at 13 Kelfield Gardens London W 10 George Egbert Brander, M R.A.F assistant medical officer, public health department London County Council

CROOK.—On Sept. 5, Hugh Walter Dowes Crook, M R C S D P M., assistant medical officer Knowle Mental Hospital, Fareham aged 36

GRANT.—On Sept. 6 at Hampstead, Leonard Grant, M D Edin formerly of New Southgate aged 70

LAWSON.—On Sept 7, at Lowestoft Hugh Lawson M R.A.F., late of Chislehurst

LISTER.—On Sept 6 at Johannesburg Sir Frederick Spencer Lister, M.R.C.S. L.R.C.P. Capetown director of the South African Institute for Medical Research aged 63

NOTES, COMMENTS AND ABSTRACTS

THEY ALSO SERVE . . . .

STANDING and waiting is at the moment the order of the day. What are all the doctors doing shut up in their hospitals ready for civilian casualties? Filling sand-bags, digging trenches, or darkening windows? At Guy's, at any rate, it was the students who were invited to turn the Park into a miniature western front (and some may interpret it as a sign of modern decadence, that the free beer supplied by the acting superintendent lasted longer than had been budgeted for)[1] At the Royal Free, it was the fair hands of the unqualified which heaped sand into bags. The doctors are at present, if not technically part of the great unemployed, at least part of the great unoccupied.

A few of us have the Napoleonic capacity for sleeping when, where, and for as long as, we like. For the rest, a few hints on passing the time pleasantly may not come amiss. Darts and billiards are apparently out of fashion, their places being taken by darts-bowls. Hospitals not blessed with tennis courts can still usually find a patch of grass where, before or after dinner, a delightful game may be played A hospital *without a shove-halfpenny board can hardly be called* a hospital. Liquid refreshment should be stored in a cool place and, if supplies are limited, the key of the cave should be placed in trustworthy hands.

But, when all is said and done, there is no better way of passing time with pleasure and profit than with a pipe and book. Shall our emergency reading be light or heavy? Charity begins at home, so for a start, we would remind our readers that buried treasure may be found inside our own covers We have known men who read Gibbon under shell-fire in the front line; with that mighty tale of revolutions, battles and sudden death as a background we see our own times in clearer perspective. Pepys, too, in the unbowdlerised version, is a sound piece of A.R.P. He lived, as we must now live, in day-tight compartments, extracting a maximum of pleasure from every trivial happening. Borrow selling his bibles in Spain transports us to another world. And each of these three books can stand constant interruptions and still survive.

For those who feel that in moments of relaxation a book should not strain the mind by either its matter or its method, there is always Dr. P. G. Wodehouse. His plots are intricate but they are of small importance. Sir Denison Ross recommends him to foreign students as a clue to the classics Lord Dunsany makes one's imagination boggle in "The travel tales of Mr. Joseph Jorkens." Bocaccio and O Henry have the double merit of brevity and wit. Those who turn to Stephen Leacock may like to be reminded that he also wrote "How Lincoln freed the slaves." Light reading is not necessarily fiction. Professor Trevelyan's *story of "The English revolution, 1688 to 1689"* is not only easy, but also apt. Two hundred and fifty years ago, we got through the political growing-pains which now afflict another nation. But best of all is Fisher's "History of Europe," three volumes now happily printed on India paper as one. What a feast it is! We cross the Alps with Hannibal, the Rubicon with Cæsar, the Danube with Attila, and the Vistula with Napoleon, forgetting for a time the painful necessity of crossing the Saar with Gamelin. Fisher and a gas-mask will, we hope, see us through.

TOWN AND COUNTRY NITS

THE thoughtful countryman, confronted for the first time by a hoard of miniature townsmen, is asking himself if, along with other troubles, the evacuated children may not bring pediculi. A glance at the annual reports of the school medical officers suggests that this fear is groundless. In Devon, 98 657 inspections last year revealed 2214 "unclean" heads (2 3 per cent). In East Sussex, pediculi were found in 1 9 per cent of inspected children, and in Warwickshire in 3 0 per cent. In urban areas, the figures are very similar The borough of Bermondsey records only 0 8 per cent. discovered at 105,646 inspections. In the borough of Hendon 2 7 per cent were found at 36,797 inspections. The city of Nottingham was high with 4 0 per cent. at 78,361 inspections. The complaint that the town child is dirtier than his country cousin is apparently no longer justifiable. Some say, however, that while the rural cleanliness may now be soundly based on parental pride the urban cleanliness still has the support of the de-lousing station. At the same time, in the general reshuffle, an occasional child with nits and pediculi may find its way into a home where these are unknown This appears to have happened at Kettering, where a number of evacuees, chiefly unaccompanied children, were found, in the words of the *Northampton Evening Telegraph*, to be suffering from "certain skin diseases, not dangerous, but unpleasant." The borough council actually had to open a private house for treatment of the more obstinate cases In Yorkshire, Alderman Davies, chairman of the North Riding public health *committee, is urging medical examination of evacuees* by evacuating authorities, now that the worst of the rush is over. Such a suggestion must be carefully considered before it is acted upon, for evacuation is more urgent than the detection of minor maladies. The Ministry proposes the removal from billets to empty houses of demonstrably unwelcome guests.

1. Passim, *Guy's Hosp Gaz* Sept. 9, 1939, p. 291

". . . The energies, the abilities, and the knowledge of each and every individual with scientific training must be directed without remission to the service of the Allied cause. Nevertheless, the end to be attained, and the end which science should hold ceaselessly before the eyes of the Allied peoples, is not destruction, but a constructive ideal—to ensure in the future such conditions as will make possible the advancement of all the peoples of the world without discrimination, according to the status and the traditions of each, in the light shed by reason and scientific knowledge To keep alive the aims of science in furthering the pursuit of truth in the universe and the relation of that truth to the developments of man's nature, without regard to tribal and racial distinctions, should be, indeed must be, the ultimate function of the scientific thinker, whatever may be his more immediate preoccupations"—*Nature, Lond*, Sept. 9, 1939, p. 455.

Medical Diary

TUESDAY, SEPT. 19—4 30 P.M. (Tennent Memorial Building, 38 Church Street), Dr. I Chesar Michaelson: Pressure Problems—Ocular, Cerebral and Circulatory.

Vacancies

Birmingham, Romsley Hill Sanatorium—Res. Asst M O, at rate of £240.
Bolton Co Borough, Townleys Hosp—Third asst. M O, £350. Also 4th asst M O, £250
Burnley County Borough—Sen. Asst M.O H, £800.
Chester Royal Infirmary.—2 Hon. Radiologists
Dunedin Hosp, New Zealand.—Radiotherapist, £1100
Hull Corporation Health Department—Asst. M.O H, £600
Kettering and District General Hosp—Jun. H S at rate of £150
Metropolitan Hospital, Kingsland Road, E 8.—Resident Appointments at rate of £100
Plymouth, Prince of Wales's Hosp, Greenbank Road—H S, at rate of £120.
Plymouth, Prince of Wales's Hosp—Sen and Jun H S's for Devonport section, at rate of £130 and £120 respectively.
Preston County Borough, Sharoe Green Hosp—Jun. Asst R M O. at rate of £100.
Reading, Royal Berkshire Hosp—Res H S., H P., and Cas O, each at rate of £150
Royal Chest Hospital, City Road, E C.1—H P. at rate of £100
St. Marylebone Borough Council.—Public vaccinators, £90 and £30 approx. (according to district)
Tottenham Borough—Temporary Asst M O.H (A R P.), £550
Watford Borough—Temporary Asst M O H, £600
Willesden General Hosp—Cas. O, at rate of £100.

BY DUNCAN C L FITZWILLIAMS, C.M.G., M.D. Edin., F.R.C.S.

SENIOR SURGEON TO ST MARY'S HOSPITAL, SURGEON TO MOUNT VERNON HOSPITAL AND THE RADIUM INSTITUTE, LONDON

AN Irishman might say that the problem of inoperable carcinoma of the rectum can only be solved by diagnosing it at a sufficiently early stage to render it operable. He would be right. But with some accessible and, more especially, inaccessible carcinoma for many and obvious reasons this is not possible. There must always be a considerable number of patients who are inoperable before they come to the surgeon. Early diagnosis is of the greatest importance, but we deal here with patients who for one cause or another have passed beyond this stage.

SYMPTOMS

In late cases the symptoms complained of are as follows. There is looseness of the bowels, with three, four, or more motions a day; this is the most significant symptom even in early cases. It is especially noticeable with the prominent redundant growth low down in the bowel. Quantities of mucus are passed in the stools, which sometimes consist of little else; it is the mucus that causes the repeated motions. The presence of a tumour low down in the bowel gives rise to that feeling of dissatisfaction when the motion has been passed, as if there were more to come. The presence of blood is variable; it is often present in small quantities but sometimes only in attacks, when much may be lost.

Pain is always a late sign and is of two kinds. There is colic, especially severe with a scirrhous growth, constricting the bowel and narrowing the lumen as if a tape had been tied round it ("string stricture"). This comes on in bouts and is accompanied by rumblings and gurglings—what the patient terms wind, which, if he is observant, he will notice gradually becoming more and more pronounced. Then there is the other kind of pain, the dull ache which is always present. This is partly due to the ulceration and partly to the extension outside the bowel wall involving the neighbouring structures, especially the nerves.

The other symptoms include loss of weight, anæmia from loss of blood, and, more especially, toxæmia due to absorption from the bowel, and a loss of appetite may have become apparent. In advanced cases these symptoms are all found, though they vary in severity from case to case.

DIAGNOSIS

Diagnosis is simple and can usually be made by the finger in the rectum. Less often the sigmoidoscope is needed, and still less often we have to rely on the barium enema and radiography, but both these methods may at times be indispensable. Diagnosis by the barium enema is best made as the fluid runs in and the bowel is manipulated by the hand pressing on the abdomen. It is advisable for the surgeon to be present and to see this done. Photographs are taken as a record of the obstruction and are useful for showing to the relations and even the patient as evidence of what is termed "his stricture." Even when the finger can reach and diagnose the growth, a barium enema is most useful and should always be given. The information thus obtained may save much time if an operation is carried out.

Diagnosis at this stage, after the patient has been ailing for some time, is not quite the shock it is when made early while the patient is yet in robust health, but still it is not pleasant, especially as one cannot be open and frank with the patient. The relations, with whom one is unreserved as to the state of things, and what ought to be done, and the best way of doing it, are often for a while terrified by the catastrophe which they realise is about to befall them.

TREATMENT

A decision has now to be made as to what is the best thing to do, and it is not easy to decide at a moment's notice. It is better for the surgeon to have a talk both with the doctor and with the relations, first separately and then together, before deciding what to advise the patient, and then to tell the people to talk the matter over with the doctor who is, after all, the person on whom they are going to rely more and more in the future and the one whose advice they will most readily follow. It is necessary for the surgeon to have in his mind clearly the possibilities of the case, and the family should also be made conversant with them.

To begin with, the radical operation in the ordinary case in the hands of the most expert has a case mortality of 1 in 5. In the hands of the surgeons of the smaller provincial and cottage hospitals it has a mortality which is presumably much higher. The operation therefore should be considered to be one with a high fatality rate and never to be undertaken lightly. We are only dealing here with the late case.

Next the general health of the patient should be gauged with accuracy. Experience has impressed upon me that the age of 65 is the limit beyond which it is unwise to operate. If the general health has been undermined by the disease, if there is loss of weight, if loss of blood has caused anæmia, or if the patient has become toxic from bowel absorption, the operation should not be urged, and if the cardiac or vascular system is not first class, or if there is diabetes or renal disease, the operation is out of the question. From this it will be seen that there will be many cases which will require some other form of treatment.

Let us discuss the advice we give to a patient who is young and in fair general health, and in whom we are not yet sure that the disease is irremovable. The best thing to do is to perform a laparotomy and to explore the condition through a median incision below the umbilicus. The growth is examined as to its nature, its fixity, and its extensions, together with the glands draining the region, and the possible peritoneal extensions, and above all the presence or absence of metastases in the liver *must* be ascertained.

When we have decided that the state of affairs is such that radical removal cannot be performed, a colostomy should be arranged through a separate opening on the left side. The patient *should* be warned beforehand of the possibility of having a colostomy. The colostomy should be made through a large skin incision and a small incision in the muscles, which should be split. The bowel is pulled up as far as possible, so that the opening is as near the growth as may be and there is a more or less straight passage

along the gut to the growth. This is important for future treatment

The idea of a colostomy is repugnant to most people, but it is astonishing how little a well-managed colostomy incommodes the possessor My patients are all recommended not to use a catheter to wash out the bowel, but to use a stomach-tube, which they pass right round to the cæcum and so wash out the large bowel completely, they then empty it of fluid and are safe for the next twenty-four hours During this time the large bowel gradually fills again, and it should always be emptied at the same hour each day. Nothing could be simpler, and nothing could be more effective A piece of lint and a flat rubber pad are all that is worn over the colostomy opening

A word may be said about the advantages of a colostomy, which in my opinion are very great To begin with, the rate of growth of a carcinoma depends on its blood-supply, vascular tumours grow quickly, whereas avascular tumours grow slowly. Fæcal material passing over a tumour irritates it, causes it to bleed and secrete mucus, and so increases the vascularity and therefore the rapidity of the growth. A colostomy confers freedom from all such irritation. The constant passage of mucus is lessened, the bleeding is allayed, and the general health and well-being are much improved. The removal of the obstruction removes the toxæmia, and all colicky pains disappear; these are great assets to the comfort of the patient, and the outlook on life improves immensely. For these reasons I am in favour of performing a colostomy in every inoperable case

Now let us turn to the patient whose general health, age, or the condition of the growth obviously precludes the possibility of a radical operation. Here we have to make up our minds whether we recommend the patient to have a colostomy performed at once, or wait until symptoms develop which compel us to perform one *In many cases* this is difficult to decide My opinion is that the facts had better be laid before the patient, who should talk the matter over with his wife and his doctor and then decide for himself. I favour a colostomy for the reasons given above, but it is better to let the patient be master of his own fate rather than to urge him in any one direction

Should he decide on a colostomy, the opening can be made in the left iliac fossa. The interior of of the abdomen can be explored through the incision and the inoperability confirmed. There is more liability to the development of a hernia through a large incision in the muscles at this point than if the bowel is brought up through a small separate opening. Again the opening in the bowel should be as near to the tumour as possible for subsequent treatment.

In many cases the age is so advanced, the system so undermined, and the disease so extensive, that it is questionable whether it is worth while doing anything. In these cases a very useful method of treatment can be carried out with conspicuous success in most instances and amelioration of the symptoms in all—namely, the application of radium to the growth It should be made plain to the relations why radium is used No hope of cure should be expressed, but a confidence may be given as to the relief from, and the avoidance of, certain most unpleasant symptoms In most cases too there is a prolongation of life, and a not too unpleasant life. There may even be a return to work for a time. Should the miracle happen, they can attribute it to whom and what they please

What are the symptoms likely to develop if nothing is done? These we find are just those which give the most unpleasant features to carcinoma of the rectum, they are due to the spread of the disease to neighbouring parts We have mentioned the constant aching pain of ulceration When this extends backwards to the sacrum and outwards to the sacral nerves, it is greatly aggravated, shoots down the back of the thighs, and becomes almost intolerable; large doses of sedatives are required to control it Even more misery is caused by extension forwards in the male to the prostate and bladder, causing genito-urinary distress, in the female to the vagina and uterus When genito urinary symptoms are added to the patient's misery, he has no peace, and life becomes unbearable.

Radium will materially cut down the blood-supply of the tumour According to B D Pullinger and other workers, restriction of the blood-supply is one of the chief modes of action of radium Owing to its action in stopping the mitosis of cells, the growth of the tumour will cease for a time, and fibrous tissue will form Under its influence the tumour will become less vascular, smaller, and more fibrotic, and shrinkage will continue for some time The application of radium is then repeated How far this shrinkage will continue depends on the dose, its accuracy, and the number of applications. A good deal of this depends again on the coöperation of the patient Before the dosage of radium was as well understood as it is today grave disadvantages might follow its use

A friend of mine was treated by radium alone, which was inserted interstitially between the bowel and the sacrum in a large and concentrated dose, and the radium was inadequately protected The result was that the bowel sloughed, the bone necrosed, and there was a constant leakage of bowel contents over a most sensitive sloughing area which had no chance of healing. He died worn out with pain the result of his treatment rather than from the disease from which he suffered.

This was not a rare phenomenon in the early days, when knowledge only advanced by the slow process of trial and error It was these results and similar ones in other parts of the body which gave radium the bad name from which it is only now recovering Now there is no contra-indication to radium given in the right dose adequately protected Nothing but good can come from its use.

The treatment, now more or less stereotyped after a long experience of trial and error, is as follows:—

Well-screened and protected radium 20–30 mg. is mounted on four strands of twisted copper wire, gauge 23, which is stiff enough for manipulative purposes and yet perfectly flexible This is inserted into the anus and guided by the finger or through a sigmoidoscope into the stricture, and the end is coiled up and fixed to the buttock with strapping; it is left in place for twelve hours It is then removed and inserted for twelve hours into the lower opening of the colostomy, a specially narrow sigmoidoscope being used to place it into position. The importance of having the colostomy opening as near the tumour as possible now becomes apparent. The coiled end of the wire is fastened to the anterior abdominal wall with strapping, one or two days' interval is allowed, and the procedure is repeated at both the anus and the colostomy opening. In the female an additional port of entry for growths low down is obtained through the vagina, the bladder being packed forwards.

In this way a dose of 1000–2500 mg hours is given to the tumour, which is ample to begin with. Experience alone enables one to estimate the dose according

to the size of the tumour This is repeated in fourteen days and again in a month's time Very shortly a considerable change will be noted in the tumour, a two months' interval is allowed and then longer and longer intervals are arranged, according to the reaction desired and obtained

In many cases the growth will shrink in an extraordinary manner, and in some cases it has disappeared from the interior of the bowel, all discharge and bleeding having stopped and all pain having passed off In one or two cases—e g , cases 1 and 6—nothing can be felt except a stricture where the growth previously existed This local action is all that can be expected, though the patient may foster hopes of a cure, hopes which are rightly encouraged by the relations and the doctor, but, if extension has already taken place to the glands, or if there are metastases already in the liver, these must take their course At the same time the patient will be spared the really disagreeable features of the disease Later, radium applications are required only if there is any return of local activity, as shown by a return or increase in the discharge, the bleeding, or the pain Most of the painful aspects of the disease are thus eliminated If, however, pain becomes a feature and cannot be controlled by sedatives, a few doses of deep X ray therapy should be tried—the kind of treatment does not seem to be of importance This sometimes has a considerable effect in diminishing the pain , more than this cannot be expected in these advanced cases

The end of carcinoma of the rectum which pursues its way unchecked is a mournful and sad affair and sedatives are needed in increasing quantities , but if the local extension can be checked the disease does not assume the same terrible and repulsive aspects Death from internal metastases in the liver and elsewhere is not a long nor a very unpleasant process

The following cases illustrate most of the points mentioned, and the results are considered highly satisfactory

CASE RECORDS

CASE 1 —A woman, aged 59, had been ailing more than a year, with spasms in the abdomen, loss of weight, and the passage of mucus and blood, and had been treated with vaccines for colitis In the last three weeks she had had wind, gurgling and violent spasms On examination she was anæmic and appeared toxæmic with visible peristalsis and a tense tumour felt in the left iliac fossa Sigmoidoscopy revealed nothing Radiography showed a stricture in the pelvic colon

At laparotomy on June 8 1933, were found a large tumour in the pelvis adherent to the wall and irremovable, a few glands close by and a nodule of uncertain nature in the liver Colostomy was performed Radium was applied twice during convalescence, and four times during the next eighteen months The patient gained weight steadily and was restored to health From 1936 to 1939 she had four more applications in smaller doses The colostomy opening had to be enlarged but otherwise gives no trouble The growth has shrunk to a tight hard stricture The patient is 2 st heavier than she was when first seen five and a half years ago

CASE 2 —A man, aged 62, was first seen on Oct 21, 1933, with a six months history of bowel upset, with the passage of two to four motions a day, containing mucus and sometimes a tinge of blood He had lost 2 st during the last year Colic and rumblings had increased of late, and there was severe constant aching pain Radiography suggested a bony tumour low down in the pelvis On examination he was pale, anxious looking, and stout, with a distended abdomen Per rectum a growth was felt with the finger tip

Laparotomy in the Royal Masonic Hospital revealed a fixed inoperable mass with extensive spread and large glands. Colostomy was performed Radium was applied during convalescence Subsequently radium was applied twice, with a gradual cessation of symptoms The patient gradually failed and died in November, 1934

CASE 3 —A woman, aged 60 was seen on April 10, 1930, with definite symptoms for more than two years with constant pain and loss of weight, but her illness had not been diagnosed On examination she was still a stout person Per rectum a large cauliflower-like growth was found, occupying the lumen of a distended rectum, well within the reach of the finger

Laparotomy showed that the growth was fixed to the floor of the pelvis, and masses of glands were felt over the common iliac vessels Nothing was felt in the liver Colostomy was performed Radium was applied through the vagina, the anus, and the colostomy In two months the growth became much smaller and her general condition improved immensely In the next eighteen months she had three more applications of radium, her growth shrivelled to insignificance her symptoms ameliorated, and she was fairly comfortable A turn then came, and she went downhill rapidly and died in February, 1932.

CASE 4 —A woman, aged 75, seen on Jan 4, 1933, had suffered from wind for six months She used to be very active but was now no longer so She always took aperients, had noticed mucus and even blood in her stools, and thought she had piles She had lost a little weight On examination she was thin, anæmic, and appeared toxæmic A thick rigid colon was felt on the left side, the cæcum was distended, and peristalsis was active Nothing abnormal was felt per rectum Sigmoidoscopy showed a fungating stricture about 8 in from the anus Obstruction seemed imminent

Laparotomy revealed dense adhesions round the mass, hard glands, liver free, colon packed with fæces Colostomy was performed Nothing could be obtained from the colostomy opening but a few hard masses in spite of all treatment On the 12th vomiting and urgent symptoms started The patient was washed out and "quarried" out with the handle of a dessert-spoon two or three times a day, a little being brought away each time, and oil enemas were given She was acutely ill, but it was not until the 21th that the last solid masses were cleared away, the bowel could be washed free and the abdomen at last became flaccid The vomiting and colic then stopped During convalescence radium was given through the vagina the anus, and the colostomy, and thereafter repeated at intervals Her health improved, and during the year she became more energetic and attended social functions, such as Ascot and the opera The growth discharged very little and gave her little trouble, but after eighteen months her appetite failed, and she went downhill rapidly, dying in May, 1934

CASE 5 —A man, aged 65 seen on April 24, 1933, said that his bowels had been regular until two months ago when they became frequent and no longer felt as if they emptied Mucus and blood had been noted lately with griping pains and loss of weight On examination nothing abnormal was found in the abdomen Per rectum a stricture was felt about 3 in from the anus, ulcerated at one side

At laparotomy in the Royal Masonic Hospital the condition was thought to be operable no glands were felt and there was nothing abnormal in his liver He then ran a temperature and developed lung trouble and the radiologist reported a metastasis in the right lung, but both Dr Chas Box and I thought it was inflammatory, and later it cleared up Nevertheless this made us think that radical operation was inadvisable Radium was given and he gradually

improved in health, gained weight, and returned to his work as a salesman He was in hospital for week-ends four times in 1934 and had radium He remained in fair health until the end, when he developed generalised carcinoma and required morphine. He died on Oct 9, 1935

CASE 6.—A man, aged 59, seen on May 9, 1935, said that a few months ago he had had severe pain in the lower part of the abdomen, vomiting, and a temperature. This passed off, but the bowels had never been normal since, and he always had wind and colic. Mucus and blood had not been noticed, but he had lost much weight. Radiography after a barium enema showed a stricture in the lower part of the pelvic colon.

Laparotomy was performed in the Royal Masonic Hospital. The pelvis contained a growth attached to the anterior wall, enlarged and hard glands were found in the mesentery, and nothing abnormal in the liver. The condition was inoperable. Colostomy was performed and radium given. In 1936 he had radium three times, and by the middle of the year he had returned to work in the coal trade and was motoring 600 miles a week. In 1937 an obvious stricture in the bowel seen through the sigmoidoscope was all the evidence remaining; he was 3 st. heavier than when first seen In 1938 he had two applications of radium, the last in December He is still at work and looks and feels well. The colostomy "gives no trouble to him, so long as he takes trouble with it."

CASE 7.—A man, aged 58, seen on Dec. 19, 1933, had had typical symptoms for some months and was diagnosed as cancer of the rectum before I saw him. Laparotomy in the Royal Masonic Hospital showed that the condition was inoperable, and radium was given. During 1934 he had three more applications of radium, his health improved, and he returned to work in March of that year. He remained well until the end of 1937, when he developed generalised carcinoma. He died in the early part of 1938

CASE 8.—A woman, aged 64, was admitted to St. Mary's Hospital in February, 1934 She could not say when symptoms started. There had been frequency of bowels and passage of mucus and blood. The patient had been losing weight On examination per rectum a growth was found well within reach of the finger.

Laparotomy revealed a fixed growth adherent to the neighbouring structures. Nothing abnormal was felt in the liver. A colostomy was performed and radium applied Later, radium was given on five separate occasions. In March, 1939, the patient felt and looked well and did her own housework unaided. A shrivelled growth could still be felt, but the mucous membrane over it appeared healthy. Sometimes there was a slight discharge but otherwise there were no symptoms. The patient is still well and says that her colostomy never bothers her.

SUMMARY

(1) The symptoms of inoperable carcinoma of the rectum are (*a*) frequency of defæcation, with the passage of mucus and, occasionally, blood; (*b*) pain, which consists both of spasmodic severe colic, associated with increasing rumblings and gurglings, especially in scirrhous carcinoma, and of a dull constant aching, due partly to ulceration and partly to extension to adjacent structures, especially nerves; (*c*) loss of weight, (*d*) anæmia, (*e*) toxæmia, and (*f*) anorexia

(2) Diagnosis is easy and can usually be made by digital rectal examination If not, sigmoidoscopy, or else radiography after a barium enema, may be necessary

(3) Treatment is more difficult Operation should not be urged if the patient is over 65, or if there is loss of weight, anæmia, or toxæmia If the cardiovascular system is not good, or if there is diabetes or renal disease, the case is inoperable If there is doubt about the inoperability, laparotomy should be performed to enable the growth to be examined. If the growth then proves to be irremovable, a left colostomy should be made If laparotomy is not necessary to confirm inoperability, the patient should be left to decide whether to have a colostomy or not, after having a full explanation from the surgeon In cases in which even a colostomy seems to be contra-indicated palliation of symptoms and prolongation of life can be aided by the application of radium

TREATMENT OF EPILEPSY WITH SODIUM DIPHENYL HYDANTOINATE

BY DENIS WILLIAMS, M.D., M.Sc.Manc, M.R.C.P.
REGISTRAR AT THE NATIONAL HOSPITAL, QUEEN SQUARE, LONDON

LAST year Merritt and Putnam (1938) reported favourably on a trial of sodium diphenyl hydantoinate in epilepsy In their series toxic symptoms were seen *in 15 per cent. of cases, though they were mainly* transient and without danger. The reports that have since appeared have shown this substance, although of great benefit in epilepsy, to be more toxic than other established and efficacious drugs, whose toxicity in therapeutic doses is of little moment To justify its use in treating epilepsy it would therefore have to produce a much greater anticonvulsant effect than the other drugs, and would have to succeed where other therapeutic methods had failed For this reason it was decided to carry out a therapeutic trial on a selected group of epileptic patients who had been closely followed for many years, and whose condition had not been greatly influenced by other forms of treatment

MATERIAL

The ninety-one subjects of this inquiry were patients attending the National Hospital, Queen Square They all lived a fairly normal existence at home, many earning their living and others being dependent on their relatives. They therefore represented the type of epileptic patient met in the general population, and the conditions under which they were treated more closely approached those found in private practice than in institutions. The results of treatment are so far inconclusive in eight patients, so that eighty-three are included in the report

These patients had been observed regularly in the National Hospital for periods ranging from 6 months to 31 years with an average of 6·4 years, thirty-eight had been admitted to the hospital for investigation and stabilisation of treatment, and since discharge all but eleven of these had been observed regularly as outpatients An exact record of the course of the disease and of its response to alterations in treatment over many years was thus available in all cases As far as possible patients were selected for the trial whose epilepsy had progressed steadily in severity in spite of carefully controlled treatment. In all cases the response to the previous treatment was proving unsatisfactory when treatment with sodium diphenyl hydantoinate was begun The patients' ages ranged from 9 to 59 years, and epileptic fits had been present for 1 to 45 years, the average length of history being 14 years I am indebted to the physicians under whose care they were for permission to investigate the cases and for their coöperation.

In many patients fits had been observed in hospital, in others the history was conclusive, and in a few

whose accounts were inconclusive the diagnosis was made by electro encephalography The incidence of the different types of epilepsy was as follows —

Type of fit	*Patients*
Grand mal	72
Petit mal	35
Psychomotor	11
Grand mal and petit mal	28
Grand mal and psychomotor	7

As would be expected in such a series every orthodox form of treatment had been used After investigations, including encephalography and ventriculography, craniotomy had been performed in a few cases In some, ketogenic diets, water and salt elimination, snake venom and other methods of treatment had been used with varying success, but in all cases, before sodium diphenyl hydantoinate was used, various combinations of phenobarbital and allied barbiturates, with mixtures containing bromides, borax and belladonna, had been given a long trial The most usual dosage was gr 2–3 of phenobarbital with gr 30–40 of bromide and gr 20–30 of borax daily, but some patients received far larger doses than these

DOSAGE AND RESULTS

The longest continuous period of treatment with sodium diphenyl hydantoinate was 10 months, the shortest 6 weeks, the average duration in eighty three cases being 4 1 months Epanutin (P.D & Co) or sodium diphenyl hydantoinate (B D H) was given in capsules of 0 1 gramme An initial daily dose of 0 2 g or 0 3 g was slowly increased, and 0 6 g daily was given in some cases Phenobarbital and bromides were continued in decreasing doses during the period of substitution, and, as will be shown later, it was sometimes necessary to reduce the dose of sodium diphenyl hydantoinate and to supplement it with other anticonvulsants After trial of the drug alone the following combinations were found to give an optimum therapeutic effect

	Cases
Sodium diphenyl hydantoinate alone	52
with phenobarbital	9
with bromides	16
with phenobarbital and bromides	6

The results of treatment over an average period of 4 1 months are shown in the table which follows It is probable that some of the cases in the "relieved" group will later fall into the "improved" group, and that in time some of the beneficial effect of the drug will be lost, for experience with other anticonvulsants in this series has shown that even a trivial alteration in treatment may cause many months' remission in the fits

EFFECT OF SODIUM DIPHENYL HYDANTOINATE ON THE INCIDENCE OF DIFFERENT TYPES OF EPILEPSY

Result	Grand mal	Petit mal	Psycho motor	Mixed
	Number and percentage			
Relieved	15 (20 8)	6 (17 1)	1 (9 1)	4 (14 3)
Improved	42 (58 3)	16 (45 7)	4 (36 4)	17 (60 7)
Unchanged	10 (13 3)	9 (25 7)	4 (36 4)	5 (17 8)
Worse	5 (6 5)	4 (11 4)	0 (0)	2 (7 1)
Total	72 (100)	35 (100)	11 (100)	28 (100)

Grouping together those cases which were improved, it is seen that 79 1 per cent of subjects with grand mal and 62 8 per cent with petit mal were benefited In assessing this extremely good result it must be remembered that although the cases were of long standing and the fits had progressed in severity in spite of continuous treatment, the comparison was made between a newly exhibited drug and others which had been taken for months or years It is probable that if the initial effects of treatment with bromides and phenobarbital could have been compared the contrast would not have been nearly so striking, for some of the case histories show similar remissions when other forms of treatment were first begun

A group of cases showed a dramatic and maintained improvement with sodium diphenyl hydantoinate A detailed report of one of these has already been published (Williams 1939) This patient had had fits every day since infancy, but has been almost normal since beginning treatment with the drug 10 months ago ' Fifteen such subjects (18 per cent) have been selected from the series in view of the long history of frequent and unremitting grand mal and petit mal epilepsy which was cut short with sodium diphenyl hydantoinate In these fifteen there had been many fits each day for from 8 to 45 years (average 19 8 years) and complete or relative freedom has now been produced for an average of 5 months None of these patients had had such a remission before

In some cases no improvement was found with 0 2 or 0 3 g daily, but the addition of 0·1 g caused great improvement It was later found that the addition of 0 1 g above the therapeutic dose gave toxic symptoms, or that in time continuation of an effective dose of 0 4 g or more daily produced varying degrees of toxicity No patient receiving 0 5 g or more daily was free from toxic symptoms This suggested that the margin of safety between an adequate therapeutic dose and the minimal toxic dose in these cases was 0 1 g or less This observation was so repeatedly made in the present series that it seemed that the anticonvulsant effect might well be the presenting sign of toxicity in subjects receiving more than 0 3 g daily

In eight cases it was noticed by the patients or their relatives that although the fits had been greatly diminished in frequency since beginning the new treatment they had increased in intensity or had changed in character Some of these patients were so distressed at the severity of the fits that they preferred to have their former more frequent but milder attacks and asked to have their previous treatment replaced In subjects whose attacks had been greatly reduced in frequency many weeks of complete freedom were sometimes broken by isolated episodes when there were several severe attacks within a few hours One of these patients died in status epilepticus while receiving 0 5 g daily It seems that the drug raises the convulsive threshold but has little depressant effect on fits which have managed to cross that threshold An account of two patients who died in status will illustrate this effect

CASE 1 — A woman aged 30 had attended the hospital regularly for 10 years and had had major and minor fits for 7 years before that There were no gross physical abnormalities her general health had been good and her family history uneventful Before treatment she had had major fits on the average about once a fortnight but occasionally as many as four a day There were many minor attacks each day The major fits were well controlled and the minor were reduced to ten to twenty a month with phenobarbital gr 1 and sodium bromide gr 10 t d s This improvement continued for 2 years but the fits then increased again and when treatment with hydantoinate was started she was having fifty to sixty minor attacks with occasional major fits

each month, in spite of receiving phenobarbital gr. 4, sodium bromide gr 60 and borax gr. 30 daily. For a week 0 1 g. of sodium diphenyl hydantoinate was given with phenobarbital gr ¼ and sodium bromide gr. 10 three times a day. The next week 0 4 g of the hydantoinate and gr 1¼ of phenobarbital were given daily. The minor attacks fell to three a week. A week after beginning treatment the patient complained of itching, and a generalised morbilliform rash with petechiæ appeared in the flexures and on the palms. There were no other toxic signs, the tongue was clean, there was no adenitis, and the temperature, blood-count and urine were normal. The rash faded in 6 days with some desquamation and brown pigmentation in the flexures, and the patient felt well.

Treatment was continued unchanged for 3 weeks and the dose was then slowly increased to 0·6 g with sodium bromide gr 30 daily With this dose the attacks ceased completely Further toxic symptoms arose 7 weeks after treatment with sodium diphenyl hydantoinate had been begun. There was nausea, vomiting and anorexia for 4 days. The patient felt giddy and light-headed and complained of tremor, an unsteady gait and double vision. On examination the skin, tongue and mucosæ were normal. The patient was pale and looked ill She had ataxia, rombergism, fine nystagmus in all directions, a fine terminal tremor of the fingers and coarse bilateral intention tremor. The deep reflexes were equal and very brisk, the abdominals present and the plantars flexor. There were no other physical abnormalities and the blood-count and urine were normal.

The drug was discontinued for 3 days and a reduced dose of 0·5 g daily was then given All the symptoms and signs disappeared in 4 days. The patient felt well and was free from fits for 5 weeks on this dose, when she had five major fits in one day. She went into status epilepticus 2 days later and was admitted to hospital She continued to have major convulsions every 10–20 min in spite of paraldehyde, phenobarbital, magnesium sulphate and morphia. She died in coma the next morning, the fits having continued without interruption No gross lesions were found at autopsy.

CASE 2.—A woman aged 27 had had between seventy and a hundred grand-mal fits a year without remissions for 12 years. She had received continuous treatment at the hospital Hydantoinate was given for 9 months and the fits ceased, except for three outbursts in each of which nine to twelve fits occurred within a week. She had had no fits at all for 2 months while receiving 0 4 g of hydantoinate and gr. 30 of sodium bromide a day. She then entered status epilepticus, was admitted to hospital and died in two days, with a terminal bronchopneumonia

THERAPEUTIC EFFECT AND TOXIC SYMPTOMS

It was usual for patients to say that they felt less sleepy, that they were more active and that they had a sense of well-being which was absent with large doses of bromides and phenobarbital Bromide acne cleared up rapidly and the general demeanour of many of the patients suggested greater awareness and alertness On the other hand, relatives complained of truculence and aggression, and during observation in hospital behaviour disturbances occurred which may have been due to removal of the sedative action of the barbiturates, but which might also be attributed to a toxic effect of sodium diphenyl hydantoinate

The drug caused symptoms and signs of toxicity in 36 per cent. of the eighty-three cases The toxic effects closely resembled those described by Merritt and Putnam Sixteen patients (19 per cent.) developed early symptoms 4–10 days after beginning treatment; these were transient and slight and were produced by relatively small doses There was generalised pruritus, increased by warmth, with skin eruptions ranging from a slight erythema to a severe generalised macular eruption with petechial hæmorrhages leading in 4–6 days to a branny desquamation with faint brown staining A mild pyrexia reaching 99 8° to 100 2° F accompanied the rashes in two inpatients who were more closely observed than the outpatients, and throbbing bifrontal headaches, anorexia and slight nausea were also noticed at this stage These symptoms were observed separately in different patients They were unassociated with any other physical abnormalities, and blood and urinary examinations were normal

Late symptoms were associated with larger doses (0 4–0 6 g daily) and arose 6–12 weeks after beginning treatment They usually followed closely on an increase in dosage They were as follows.—

Alimentary.—Anorexia with lethargy, continuous nausea, epigastric discomfort, vomiting after food, furred tongue and constipation These symptoms have been attributed to the alkalinity of the drug and are said to be minimised by giving it after meals No changes like those described by Kimball (1939) were found in the gums

Nervous.—The following symptoms were met with Bifrontal headaches, pallor, lethargy, bilateral ptosis, blurring of vision, diplopia, ataxia and fine tremor of the fingers with incoördination in the hands Abnormal signs were fine nystagmus in all directions, terminal finger tremors, slight incoördination, gross ataxia, with rombergism and extremely brisk tendon jerks These symptoms disappeared in all cases within 3 days of stopping treatment and did not recur when treatment was recommenced with the dose reduced by 0 1 g daily.

Mental.—Irritability with sullen restlessness, leading to unprovoked aggression, was reported by relatives of outpatients and observed in three patients in hospital The following is an account of one of these cases:—

CASE 3.—A man of 24 had had grand mal fits for 10 years He often had several in one day, but there were remissions of several months from time to time He was admitted to hospital in status epilepticus and in spite of large doses of phenobarbital and magnesium sulphate he had 30 and 40 grand mal attacks on successive days. He was then given 0 3 g. and later 0 5 g. of hydantoinate and gr. 3 of phenobarbital daily. The fits fell from 40 to less than 1 a day After a few days he became irrational, truculent and aggressive to the nursing staff and patients. The hydantoinate was replaced by gr 30 of sodium bromide after 13 days and in a day the patient became quiet, cooperative, and friendly with the other patients and staff He seemed mentally normal, but had many more fits After 12 days 0 5 g. of hydantoinate was again used instead of bromides The fits ceased, but he became abusive and difficult and made an unprovoked attack on another patient. Hydantoinate was therefore discontinued and he became mentally normal again

Cardiac.—Three patients who had no history of cardiac or renal disease developed changes in cardiac rate during the time that other toxic signs were present.

One patient, aged 20, had a simple bradycardia of 52 per min 3 months after beginning treatment Another, aged 58, had a bradycardia of 14 per min. with very frequent ventricular extrasystoles 5 weeks after starting treatment with hydantoinate. The patient complained of weakness, breathlessness, and swelling of the ankles, and showed cardiac dilatation, inversion of the T wave, and clinical signs of cardiac insufficiency. The blood-counts and urinary examinations of these patients showed no abnormality. They recovered rapidly when the dose was reduced and a week later their pulse-rates were 80 and 72 respectively. There were then no other toxic symptoms.

The third patient, aged 34, had his first attack of paroxysmal tachycardia on the way to hospital, two months after beginning treatment When seen the apex was in the anterior axillary line, and the heart rate was 180 In this case the attack of paroxysmal tachycardia may merely have been coincidental.

DISCUSSION

Except for the greater frequency and variety of toxic symptoms encountered, the results of this trial are similar to those reported by Merritt and Putnam The subjects had all ceased to respond to routine treatment with anticonvulsants and the results in some cases show that the drug may be of great value when other anticonvulsants have failed The less encouraging results in other cases, and especially in the 30 per cent in whom the drug caused toxic symptoms, indicate that it should not replace the more reliable but less spectacular anti convulsants at the beginning of treatment The impression gained during the trial was that in the treatment of epilepsy, after all investigations have been undertaken to exclude a remediable cause, the well established anticonvulsants—bromide, borax, belladonna and barbiturates (phenobarbital)—should first be used If these fail, treatment with sodium diphenyl hydantoinate may be of benefit If relief is not obtained with doses of less than 0 5 g daily it will probably be wise in most cases to discontinue the drug or to supplement it with other anticonvulsants, for in very resistant cases more satisfactory therapeutic results were obtained with fewer toxic effects by supplementary treatment with phenobarbital or bromides Although the toxic symptoms do not seem to be dangerous, the small difference between the therapeutic and toxic doses calls for careful administration

It is interesting to compare the pharmacological actions of sodium diphenyl hydantoinate with those of the other anticonvulsants It has been shown that with sodium diphenyl hydantoinate a great reduction in the number of fits is sometimes accompanied by isolated outbursts of severe attacks The optimum therapeutic dose closely approaches the toxic, and fits do not occur at all when toxic symptoms are present It seems, in fact, that the anticonvulsant effect is a close precursor of the toxic in some cases Further, the drug has little or no depressant action on the nervous system These observations suggest a completely different anticonvulsant effect from the bromides or barbiturates, for these substances seem to control epilepsy in virtue of their depressant action on the central nervous system

It may be that whereas the bromides modify the response of the nervous system to the factor initiating a convulsion the hydantoinate suppresses this cause without modifying nervous activity If so the hydantoinate would be producing its effect at an earlier stage in the epileptic process When the cause of the convulsions reaches dimensions too great to be controlled by hydantoinate, however, it seems to activate a completely undepressed nervous system, and so causes a maximal response

SUMMARY

Ninety one chronic epileptics who had ceased to respond to other anticonvulsants were treated with sodium diphenyl hydantoinate The patients all lived at home and had been under regular observation and treatment with other drugs for an average of 6 4 years The trial period ranged from 6 weeks to 10 months (average 4 1 months)

The fits were reduced in frequency in 79 per cent of the subjects with grand mal and 63 per cent of those with petit mal In 10 per cent the improvement was dramatic and has been maintained for over 5 months Toxic symptoms arose in 36 per cent and two patients died in status epilepticus while receiving the drug

The drug seems to be of value in the treatment of epilepsy in some cases when other forms of treatment have failed, but there are no indications that it should supersede the less toxic anticonvulsants in the initial stages of treatment Its administration requires careful observation of the patient

CHEMOTHERAPY OF EXPERIMENTAL ANTHRAX INFECTION

BY J C CRUICKSHANK, M B Edin., D T M, Dipl Bact
LECTURER IN BACTERIOLOGY AT THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

THE relative values of the various therapeutic agents, or surgical procedures, which have been used in the treatment of human anthrax infection are difficult to estimate since the conditions essential to satisfactory clinical trial are almost impossible to fulfil The case mortality in Great Britain from all forms of anthrax varied during the five year periods between 1901 and 1930 from 10 5 to 29 6 per cent Respiratory and alimentary anthrax are almost invariably fatal, while the mortality of the cutaneous form may vary from 3 3 to 24 3 per cent (Legge 1934) according to the site of infection The standard treatment in the past, apart from surgery, has consisted in the use of immune serum and arsenicals There appears to be a consensus of opinion that each of these reagents has a therapeutic effect but the results are greatly influenced by the site of infection and the stage at which treatment is begun

Sclavo (1903) reported that the mortality of a series of 164 cases in man treated with immune serum was 6 09 per cent in contrast to the general anthrax mortality of 24 1 per cent for all Italy during the same period, a comparison not free from possible criticism since other differential factors may have been present Eurich (1933) uses both serum and Salvarsan in cutaneous anthrax and records a mortality of 5 per cent in 200 cases but states that the relative value of the two substances is uncertain Gilbert (1935), Spencer (1934) and many others report a high proportion of recoveries in cases treated with neoarsphenamine or other arsenicals In the report (1935) on industrial anthrax of a committee of the American Public Health Association, in which various treatments are reviewed, it is concluded that the treatment of choice is immune serum, in default of which neoarsphenamine should be used, although it is again stated that the value of immune serum is not completely proved and that some deny its specificity Other treatments which have been used are injections of peptone, of acriflavine and of copper sulphate though there is no sound evidence that they are effective

The success that has been achieved in the treatment of various bacterial infections with various sulphanilamide compounds clearly justifies their trial in anthrax infections, and such trials have probably

been made during recent years. I have not, however, been able to trace any published clinical records; and it is, in any case, desirable to assess the value of these drugs in experimental infections and under controlled conditions

EXPERIMENTAL TECHNIQUE

The general plan of the experiments recorded in this paper was as follows.

The strain of *B. anthracis* used was obtained from *the Ministry of Health laboratories through the* courtesy of Dr W M Scott. It had been isolated from horse-hair and was typical in its cultural and biochemical reactions It was tested for virulence by the inoculation of 0 25 c cm of decimal dilutions in saline of a 24-hour serum broth culture subcutaneously in the left thigh of groups of mice The larger doses killed all the mice in 24–28 hours and the dilutions chosen for the tests were of the order of 10^{-3} or 10^{-4} which killed the mice usually in 2–5 days The inoculum of 0 25 c cm of the 10^{-4} dilution was found on plating to represent about 150 viable organisms. The infected mice developed a large inflammatory local lesion with œdema spreading up the flank and abdominal wall The organism could be recovered in large numbers from the local lesion, spleen and heart-blood

The mice weighed 20–26 g and were of equal *resistance in all groups, having come from the same* stock and been fed on the same diet All groups consisted of 30 or more mice.

Treatment with the various drugs was begun half an hour after infection and was usually continued for ten days Cultures were made from the local lesion, spleen and heart-blood of the majority of the mice. The control mice invariably had intense *B anthracis* septicæmia

The object of the first experiment was to find out whether sulphanilamide or M & B 693 had any effect on the course of infection Sulphanilamide was chosen as representative of the original products found effective in streptococcal and meningococcal infections, and M. & B. 693 as an example of those active in pneumonia and certain other infections For oral administration the drugs were ground in a mortar and emulsified in water, then added to an equal volume of mucilage of tragacanth so that the required dose was contained in 0 5 c cm *This was* given directly into the stomach by means of a 1 c cm. syringe fitted with a blunt-ended No 19 needle For subcutaneous injection the sulphanilamide was given in solution sterilised by autoclaving and the M & B 693 in the suspension in olive oil issued in ampoules by the manufacturers

A total of 150 mice were infected with *B. anthracis* subcutaneously, and divided into five equal groups, of which one was kept as a control. The other groups received respectively throughout the experiment daily doses of 10 mg. of sulphanilamide by mouth; 10 mg. of sulphanilamide subcutaneously, 20 mg of M. & B. 693 by mouth; and 20 mg. of M. & B 693 subcutaneously The larger dose of M & B 693 was given on account of its lower toxicity for mice, the average lethal dose being about 16 6 mg per g. (Whitby 1938) as compared with 4 mg. per g. for *sulphanilamide (Marshall 1939) For the mice used* these toxic doses would be about 330–420 mg. and

FIG. 2

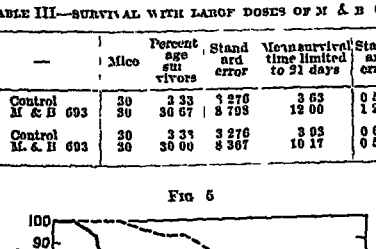
	M. & B 693	30	30 00	± 8 367	10 17	0 501

FIG 5



80–100 mg respectively In this and in subsequent experiments a group of 8–10 uninfected mice received the same doses of the drugs as the infected groups and were observed for a few weeks afterwards in order to ensure that the drugs themselves did not have any injurious action on the mice

The results are shown in table I and fig 1 None of the mice survived beyond the fourth day after infection, but life was definitely prolonged in all groups receiving treatment This is clearly shown by the figures recorded on the second day It may be inferred therefore from this experiment that both sulphanilamide and M & B 693 have some effect in delaying death from anthrax infection Further, there is no difference in the effect of oral and subcutaneous administration In the doses employed, M & B 693 is more effective than sulphanilamide

In the next experiment a 20 mg dose of sulphanilamide or M & B 693 was given by mouth twice daily as long as any mice survived so that a direct comparison of the two drugs was possible The same test was repeated and the results of the two experiments are recorded in table II (A and B) and in figs 2 and 3 Although there were still no survivors at the end of fourteen days the effect of treatment in delaying death is significant and it is also evident that M & B 693 is more effective than the same dose of sulphanilamide

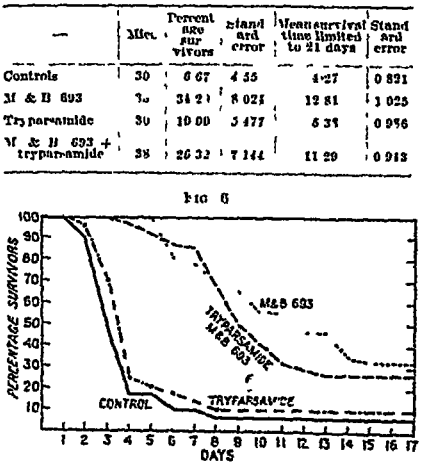
It was now desired to determine whether one could, by increasing the dose of M & B 693 to a very high level (100 mg daily), bring about a significant survival-rate in the treated group It was thought that the *concentration of* the drug in the blood might fall at some stage owing to the time elapsing between the night and morning oral doses It was therefore decided to give 60 mg by the oral route in two daily doses of 30 mg, and 40 mg daily by subcutaneous injection The oral treatment was continued for ten days and the subcutaneous injections for six days This experiment was also repeated with a slightly different infecting dose (table III A and B, figs 4 and 5) In each test there was 1 survivor amongst the controls (3 33 per cent) and there were 11 (36 67 per cent) and 9 (30 per cent) survivors in the treated groups These differences are clearly significant, as are also the differences in the mean times to death of the control and treated mice It may be stated that these large doses of M & B 693 did not appear to have any injurious effect on the mice, and there were no deaths in the uninfected group receiving the drug In a proportion of the treated mice dying after the seventh day it was not possible to isolate *B anthracis* from heart blood, spleen or site of infection, and in many of them there was no sign of any local lesion Œdema and redness at the site of infection were in fact rarely prominent in mice receiving M & B 693

Since it was established that the life of infected mice could be prolonged by moderate doses of M & B 693 and about a third of the infected mice could be saved by larger doses, it seemed of interest to try the effect of large doses of arsenical compounds which from their reported success in human anthrax might be expected to influence the experimental infection, though the published records of previous tests in the experimental disease were not encouraging (Cambouédès and Reilly 1925, Stolygyo 1927, Urbain, Theobalt and Vallée 1930, Kurotchkin and Reimann

TABLE IV—SURVIVAL WITH LARGE DOSES OF M & B 693, WITH TRYPARSAMIDE AND WITH BOTH TOGETHER

	Mice	Percentage survivors	Standard error	Mean survival time limited to 21 days	Standard error
Controls	30	6 67	4 55	4·27	0 821
M & B 693	30	34 21	± 8 021	12 81	1 025
Tryparsamide	30	10 00	5 477	6 33	0 956
M & B 693 + tryparsamide	38	26 32	± 7 144	11 29	0 913

FIG 6



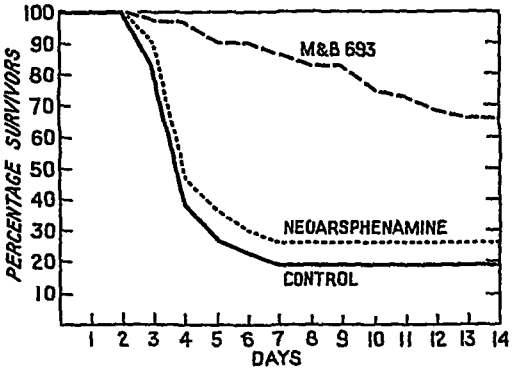
1930) Trial was first made of Tryparsamide (sodium N-phenyl glycineamide-*p*-arsonate). The maximum tolerated dose for a 20 g. mouse is given by Yorke, Murgatroyd and Hawking (1931) as 100 mg. It was determined that the mice used in the present trial would actually tolerate without ill effect the intraperitoneal injection of 20 mg in 0·5 c.cm. of sterile distilled water daily over a period of ten days. This dose was therefore employed.

In table IV and fig. 6 are shown the results of treating groups of mice for ten days with M. & B. 693 (50 mg. twice daily by mouth), with tryparsamide, and with both simultaneously. There were 6·67 per cent. of survivors in the control group, 31·43 per cent. in the group treated with M. & B. 693, 10 per cent. in those treated with tryparsamide and 26·32 per cent. in those receiving both drugs. One may deduce from these figures and those for the mean survival times that tryparsamide is without action and does not enhance the effect of M. & B. 693, which is evident in the two groups receiving it.

TABLE V—COMPARISON OF SURVIVAL WITH M. & B. 693 AND WITH NEOARSPHENAMINE

—	Mice	Percentage survivors	Standard error	Mean survival time limited to 21 days	Standard error
Controls	30	20·00	·7303	7·00	1·24
M. & B. 693	30	66·67	8·606	16·30	1·13
Neoarsphenamine	30	26·67	8·073	8·50	1·34

FIG. 7



Finally, a similar experiment was performed to determine the effect of neoarsphenamine (Neokharsivan, B. W. & Co.). This drug was shown to have an average lethal dose for 20 g. mice of about 5 mg. A dose of 1 mg. which was well tolerated by the mice was used in the test. It was given intraperitoneally in 1 c.cm. of sterile distilled water freshly boiled just before solution and injection of the drug. Another group of mice received M. & B. 693 by mouth in the same dosage as in the previous experiment. Treatment was continued for ten days. There were 30 mice in each group.

From the results which appear in table V and fig. 7, it will be noted that the mice received a rather smaller infecting dose than usual, and that 20 per cent. of the untreated mice survived. Of those treated with M. & B. 693, 66·67 per cent. survived, as compared with 26·67 per cent. of those treated with neoarsphenamine. It is thus clear that benefit has been conferred on the mice treated with M. & B. 693, and this is confirmed by the figures for the mean survival times. The effect of neoarsphenamine is entirely insignificant.

In all the foregoing experiments the mice were observed for twenty-one days, but deaths did not occur after the fifteenth day. In the last series the mice surviving on the twenty-first day, all healthy in appearance, were killed and cultures made on agar from the heart-blood and spleen. Half of the spleen was also taken into broth from which any growth after incubation was plated on agar. In no case was *B. anthracis* isolated from these mice.

DISCUSSION AND CONCLUSIONS

Of the agents tested only M. & B. 693 and sulphanilamide were found to have a beneficial action on the course of anthrax infection in mice, and of the two M. & B. 693 was more effective. The action of these drugs is not so dramatic as in streptococcal infection, but when very large doses of M. & B. 693 are given a considerable proportion of the mice survive and the curative effect is complete in the sense that the organism is not recoverable from the tissues of the mice. It is to be noted that the therapeutic doses are almost twice as large as those given by Schütze (1939) to mice in his study of plague infection. He found that a successful result was obtained by giving 80 mg. of M. & B. 693 along with the test dose and an estimated dose of 50 mg. daily which was taken with the food.

Since these mouse doses multiplied weight for weight would indicate an enormous dose of M. & B. 693 for man, the question arises as to whether any inference at all may be made from the experiments reported in regard to the use of the drug in human infections. It should, however, be noted that the experimental infection is far more severe than cutaneous anthrax in man. In all experiments but the last, all, or almost all, of the control mice died. In the last experiment, with a death-rate of 80 per cent. among the controls, the death-rate among the mice treated with M. & B. 693 was reduced to 33·3 per cent. The death-rate in cutaneous anthrax in man varies, as has been noted, between 3·3 per cent. and 24·3 per cent., and it seems at least possible that, with these milder infections, relatively smaller doses than those given in most of these experiments might have a considerable therapeutic effect. Moreover, it seems clear that M. & B. 693 has, in the mouse, a far more effective action than have arsenical compounds. Pending adequate clinical trials, it seems reasonable to conclude that the same may be true in human anthrax. Whether M. & B. 693 would exert any significant therapeutic effect in pulmonary anthrax is, of course, more doubtful, but in a disease which, untreated, appears to be uniformly fatal, it would clearly be justifiable to give unusually large doses.

Whether M. & B. 693 would enhance the effect of a specific antiserum, or how it would compare with such a serum as a therapeutic agent, are questions that must await both animal experiments and adequate trials in man.

ACTION OF THE SULPHONAMIDES IN EXPERIMENTAL ANTHRAX

By H B MAY, M R C P
ASSISTANT DIRECTOR OF THE CLINICAL LABORATORIES, LONDON HOSPITAL AND
S C BUCK, M B Camb.
ASSISTANT BACTERIOLOGIST TO THE HOSPITAL

ALTHOUGH drugs of the sulphonamide class have now been shown to be effective against a number of pathogenic bacteria besides *Streptococcus pyogenes*, no information is available as to their efficacy in anthrax infections This investigation was undertaken to find out whether there is any experimental evidence in favour of applying these drugs to human anthrax, how they compare in efficacy with commercial and other anti anthrax sera, and whether they exert any synergic action with anti serum as they do in infections due to the pneumococcus and *Str pyogenes*

TECHNIQUE

The strain of *B anthracis* used throughout was isolated from a vesicle in a case of cutaneous anthrax in an artificial manure worker It was passed repeatedly in mice until its virulence for this animal had become constant, at this stage a dose of approximately 30 bacilli injected intraperitoneally killed 90 per cent of the mice in 4 days Heart's blood was used for passage, the inoculations being made subcutaneously, throughout the investigation the strain was maintained in mice and not in artificial culture In this way its virulence for the mouse was kept more or less constant

Most investigators, such as Sterne (1937b) and Ivanovics (1937), have used fractions of an agar slope as an indication of dosage It was decided that this was too indefinite and that the approximate number of organisms used should be known Sterne (1937a) showed that capsulation of anthrax bacilli could be obtained on artificial media if the carbon dioxide concentration of the atmosphere in which it was incubated was raised to between 50 and 60 per cent This was confirmed using 14 per cent serum agar slopes and 5 per cent rabbit blood agar slopes However, it was found impossible to prevent spore formation under these conditions and it is well known that a proportion of relatively avirulent variants can be produced from a virulent strain even on first subculture on an artificial medium It was decided therefore to use the peritoneal exudate of a mouse dead overnight from intraperitoneal infection with anthrax A tenth of a 16 hour agar slope culture made from the passage strain was injected intraperitoneally and the peritoneal exudate washed out with 10 c cm of broth on the following morning The presence of a pure suspension of capsulated non-sporing anthrax bacilli was confirmed by microscopic examination Ten fold dilution of the exudate were prepared and 0 5 c cm of each dilution used with 10 c cm of agar as a poured plate for a viable count It was found that in the peritoneal exudate chains of bacilli very rarely occurred, usually the bacilli were single or in pairs and the viable counts for successive dilutions gave approximately ten fold diminution in colony counts

Sulphonamide P (B W & Co), M & B 693 and 4 4 diaminodiphenyl sulphone glucoside were used We are indebted to Dr G M Findlay for a supply of the last preparation Suspensions of the first two compounds were prepared in equal parts of water and *mucilage of tragacanth*, the sulphone was dissolved *in water*, all these were given by mouth except for one experiment in which M & B 693 was given subcutaneously as well as by mouth The doses of sulphonamide and M & B 693 were probably only accurate to ± 10 per cent owing to the difficulty of *obtaining a homogeneous stable suspension* The preparations were administered 4 hours before infection and thereafter at 24 hour intervals Sera were given intraperitoneally in a single dose of 0 5 c cm 4 hours before infection In each experiment twelve mice were treated with the drug and twelve untreated served as controls Six mice in each group were infected with approximately 300 organisms intraperitoneally in 0 5 c cm of broth and the other six received approximately 30 organisms in the same volume.

TABLE I—RESULTS WITH THREE SULPHONAMIDE DRUGS

Drug	Dose	Total dose	Infecting dose number of organisms	Treated mice † dead at end of—		Control mice † dead at end of—	
				2nd day	4th day	2nd day	4th day
Sulphonamide P (B W)	20 mg in each of 3 doses	60 mg	30 300	1 2	3 5	3 2	6 5
M & B 693	40 mg in each of 2 doses	80 mg	15 200	0 0	0 5	3 5	5 6
	60 mg by mouth, 3 doses * + 60 mg *	240 mg	20 280	0 1	5 6	3 6	6 6
Sulphone	20 mg, 2 doses	40 mg	35 400	0 2	4 4	2 3	6 6

* In olive oil subcutaneously one dose
† Each group consisted of six mice All mice died by 6th day

RESULTS

The results of experiments with the three drugs are given in Table I

The following sera were tested

(1) Sclavo's
(2) Mulford's
(3) Serum from a patient recovered from a natural infection with anthrax, *the serum being collected* three weeks after infection.
(4) A rabbit immune serum prepared by giving twelve weekly intravenous injections of the whole of a mouse peritoneal washing, sterilised with 0 5 per cent formalin and kept at 0° ± 1° C till sterile This was a fully capsulated bacterial vaccine This serum precipitated the "P" substance of the anthrax

TABLE II—PROTECTIVE ACTION OF VARIOUS ANTI ANTHRAX SERA

Serum	Infecting dose, number of organisms	Treated mice * dead on—		Control mice * dead on—	
		2nd day	4th day	2nd day	4th day
Sclavo's	15	3	6	5	6
	300	6	6	4	6
Mulford's	80	0	5	2	5
	400	6	6	5	6
Human convalescent	20	0	4	4	6
	350	2	5	4	6
Rabbit immune	20	0	2	5	6
	250	0	1	5	6

* Each group consisted of six mice.

capsule, a polymer of d(−) glutamic acid (Ivanovics and Bruckner 1938, to a titre of 1/1000. The sera were given in 0·5 c.cm. doses intraperitoneally 4 hours before infection. In the test of each serum twelve mice were treated while twelve untreated animals served as controls. The infecting doses were the same as in the experiments with the drugs. The findings in these experiments are recorded in table II.

The three remaining mice in the experiment with patient's serum and the nine remaining mice in the experiment with rabbit serum all survived.

Two experiments were carried out with a combination of M. & B. 693 and serum, 0·5 c.cm. of serum being given intraperitoneally 4 hours before infection and 40 mg. of M. & B. 693 by mouth in each of the doses, the first 4 hours before infection and the second 24 hours later. The results are summarised in table III.

TABLE III—COMBINED EFFECT OF DRUG AND SERUM

Serum	Infecting dose	Treated mice dead on—		Control mice dead on—	
		2nd day	4th day	2nd day	4th day
Human convalescent + M. & B. 693	30	0/3	1/3 *	2/3	3/3
	200	0/3	1/3 †	2/3	2/3
Immune rabbit serum + M. & B. 693	30	0/5	0/5	5/5	5/5
	250	0/5	4/5	5/5	5/5

* 2 more died on 5th day. † 1 died on 5th day.

DISCUSSION

Although there is no evidence from these experiments that any of the three chemotherapeutic preparations—sulphonamide, M. & B. 693, sulphone glucoside—had any effect, in the dosage employed, on the ultimate outcome of infection in mice with *B. anthracis*, there is some indication that the drugs were not entirely without effect. The findings at the end of 2 days showed fewer deaths among the treated mice than among the controls. And, although these differences were not sufficiently great to be significant in the case of the groups treated with sulphonamide and the sulphone, in the case of the mice treated with M. & B. 693 the differences appear to be significant. At the end of 2 days, in the first experiment with M. & B. 693, when eight out of twelve control mice were dead, all the twelve mice treated with M. & B. 693 were alive and apparently well. This suggests that M. & B. 693 had the effect of holding up temporarily the course of the infection.

With the two commercial sera most commonly used in this country there was no difference at any stage of the experiments between treated and control animals; similar findings have also been obtained by Tomcsik and Ivanovics (1938) with the sera commercially available in Hungary. The serum prepared in the rabbit, however, saved nine out of twelve mice. Since it has been show by Ivanovics (personal communication) that anti-anthrax sera capable of protecting mice may be ineffective in guineapigs and rabbits, it by no means follows that a serum conferring no protection on the mouse would be valueless in the treatment of human anthrax. Clinical experience has in fact shown (Eurich 1927, Hodgson 1928) that Sclavo's serum does exert a beneficial effect on anthrax infections in man.

The main object of these experiments with anti-anthrax sera in mice was to find out whether, with a serum protective for this animal, there is any synergic action between serum and drugs of the sulphonamide group such as has been shown for antipneumococcal sera and M. & B. 693 by Fleming (1938) and for anti-streptococcal serum and sulphanilamide by Loewenthal (1939). No such complementary action could be demonstrated, for the results obtained with the anti-anthrax rabbit serum together with M. & B. 693 were no better than with serum alone. Although there is no clear indication from this work that drugs of the sulphonamide group would be a useful adjunct to serum in the treatment of human anthrax, the fact that they, and M. & B. 693 in particular, were apparently able to hold up temporarily a rapidly invasive infection suggests that they might be of some service. Actually, while these experiments were being carried out, 2 cases of severe cutaneous anthrax were treated with M. & B. 693 and Sclavo's serum. Though both recovered, it cannot justifiably be claimed that the use of the drug played any material part in overcoming the infection.

SUMMARY

(1) M. & B. 693 and to a less extent sulphanilamide and sulphone delay death in mice infected with fully virulent capsulated non-sporing anthrax bacilli.

(2) No ultimate decrease in mortality is found by using these drugs.

(3) Two commercially available sera commonly used have no protective action for mice.

(4) The findings of Ivanovics and Bruckner, that an anti-anthrax serum prepared in the rabbit exerts a high degree of protection in mice, have been confirmed.

(5) There is no apparent increase in the protective action of serum in mice by using it in combination with M. & B. 693.

We are indebted to Prof. S. P. Bedson and Dr. P. N. Panton for help and encouragement, and to Dr. G. Ivanovics for supplying some purified "P" substance of the anthrax capsule.

COMPLETE HEART-BLOCK IN YOUNG PEOPLE

REPORT OF TWO CASES

BY HAROLD J. BOWER, M.B. Camb.

HON. ASSISTANT PHYSICIAN TO THE ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL AND TO THE SOUTHAMPTON CHILDREN'S HOSPITAL

CASES of complete heart-block in children and young people have been recorded by Archigène in 1927 (39 cases), Yater in 1929 (30 cases of congenital block); Wood and Rogers in 1932 (6 cases of congenital block); Sprague and White in 1927 (11 cases of juvenile block); Perry in 1931 (3 cases in children, 2 the result of rheumatic heart disease and 1 a sequel of an attack of diphtheria, all leading normal school lives); and Campbell and Suzman in 1934 (8 cases of congenital complete block, 7 living normal lives, 1 died of rheumatic complications). Lemann, in a review of the literature in 1933, stated that heart-block was congenital in 42 of the approximately 100 published cases.

The first case reported here was evidently the result of a severe measles infection. All the acquired

cases of persistent heart block in children due to infection are said to result from influenza, diphtheria, and rheumatic fever, this seems to be the first one reported as the result of measles The second case had severe measles at the age of three, and malignant influenza in 1918 at the age of five, so there was a source of infection which might have caused the heart block Otherwise, it must be considered as congenital A point of interest in this case is the high ventricular rate after exercise and injection of atropine gr 1/33 After exercise the ventricular rate increased from 50 to 80, the auricular rate from 90 to 100 After atropine the ventricular rate increased from 50 to 80, the auricular rate from 90 to 110

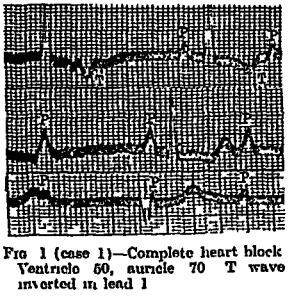

FIG 1 (case 1)—Complete heart block Ventricle 50, auricle 70 T wave inverted in lead 1

Liljestrand and Zander (1927) investigated a case, a young man of twenty one who was able to take part in strenuous games and to swim "for as long as he liked" His ventricular rate increased up to over 100 with strenuous exercise Aitken (1932) reported two cases after injection of atropine gr 1/75 In the first the ventricle increased from 62 to 94, and the auricle from 100 to 150 In the second the ventricle increased from 55 to 87, and the auricle from 100 to 137 Atropine has been shown to produce similar effects in other cases, but in some there has been no response at all

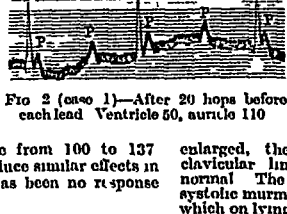

FIG 2 (case 1)—After 20 hops before each lead Ventricle 50, auricle 110

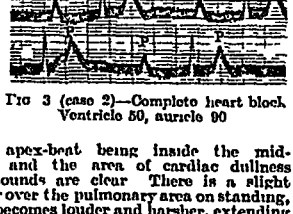

FIG 3 (case 2)—Complete heart block Ventricle 50, auricle 90

CASE 1.—A boy aged thirteen, with heart rate 56 per min At the age of three he had severe measles and is said to have nearly died His doctor noted a murmur over the heart He was kept very quiet for a long period and as he seemed well was allowed gradually to take more exercise By the time he went to his preparatory school he was able to play games and run without fatigue At the age of thirteen during an attack of influenza, the school doctor noted that there was a marked systolic murmur over the cardiac area

On examination he is a very active boy, thin and excitable, but looks healthy Heart-rate regular, 56 per min Apex-beat inside the midclavicular line, and area of cardiac dullness normal All the sounds are accentuated The first sound at the apex and the pulmonary second are more accentuated but clear There is a harsh systolic murmur best heard over the pulmonary area and audible down to the apex, both on standing and lying Blood-pressure 130/90 Radiography shows enlarged right auricle, beating 2 beats to 1 of the ventricle Exercise-tolerance 56 per min before exercise, 60 after 20 hops, and 56 after resting two minutes, response is good, with no dyspnœa (see figs 1 and 2)

CASE 2.—A youth aged nineteen, with heart rate 50 per min At the age of three he had severe measles, but was not dangerously ill In 1918 at the age of five he had severe influenza of the malignant type which was then prevalent In 1927 at the age of fourteen his doctor accepted him on the "club" In 1931 at the age of eighteen the same doctor attended him for pyrexia for a fortnight, and noting a murmur told him that his heart was wrong and he must lead a quiet life No details are available from his doctor as he has since died The young man has no shortness of breath and can cycle a 100 miles in a day with ease

On examination he looks healthy Heart is not enlarged, the apex-beat being inside the mid-clavicular line and the area of cardiac dullness normal The sounds are clear There is a slight systolic murmur over the pulmonary area on standing, which on lying becomes louder and harsher, extending over the aortic area and up to the left clavicle Blood pressure 155/85 Heart normal radiographically. Exercise tolerance 50 per min before exercise, 80 after 20 hops, and 50 two minutes after exercise, response good, with no dyspnœa (see figs 3, 4 and 5)

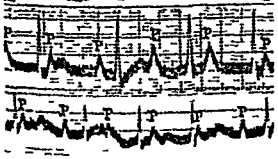

FIG 4 (case 2)—After 20 hops before each lead Ventricle 80 auricle 100

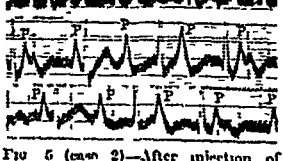

FIG 5 (case 2)—After injection of atropine gr 1/33 Ventricle 80, auricle 110

STILBŒSTROL AND ANHYDRO-OXYPROGESTERONE

THEIR EFFECTS ON MENSTRUATION AND LACTATION

BY ROBERT WENNER, M.D.,

AND

KARL JOËL, M.D.

(From the Women's Clinic of the University of Basle)

SINCE Cook, Dodds, Hewett, and Lawson (1934) reported the œstrogenic activity of synthetic compounds containing the phenanthrene ring, many attempts have been made to discover other compounds with similar properties

Dodds and Lawson (1937) showed that *p*-hydroxypropenyl-benzene, or anol, a relatively simple chemical compound containing only one benzene ring, exerted in castrated rats an œstrogenic effect similar to that of œstrone. A further compound, 4 : 4'-hydroxydiphenyl- α : β diethylstilbene, containing two benzene rings and discovered by Dodds, Golberg, Lawson, and Robinson (1938) was found to have a high œstrogenic activity both on oral and on parenteral administration. Fierz-David, Jadassohn, Uehlinger, and Monnier (1938) and several other investigators have fully confirmed the œstrogenic properties of this compound, which has been named stilbœstrol by Dodds

In the reports of animal experiments with stilbœstrol there is a unanimity of opinion on the qualitative identity of its actions with those of œstrone, although there are considerable quantitative differences

Kreitmaier and Sieckmann (1939) found stilbœstrol to be twenty times more active than œstrone and five or six times more active than œstradiol benzoate given by mouth. There is not yet complete agreement with regard to its toxicity towards animals. Whereas Kreitmaier and Sieckmann say that doses of 300 mg administered subcutaneously to a small dog produced no secondary symptoms, Loeser (1939a) found injurious effects on the adrenals and liver after large doses.

According to Loeser (1939a) stilbœstrol injected into the uterus does not stimulate the thyroid gland, whereas œstrone does Loeser suggests that this distinction may constitute a test for differentiating between endogenous and foreign œstrogenic substances.

The œstrogenic properties of stilbœstrol have also been confirmed in clinical studies

Guldberg (1938) induced menstruation in a castrate after the administration of a total of 20·25 mg. and subsequent treatment with corpus-luteum hormone. Engelhart (1938) obtained the same result with a total of 28 mg. in seven intramuscular injections

Other writers, including Loeser (1939b), Winterton and MacGregor (1939), and Bishop, Boycott, and Zuckerman (1939), emphasise that the action of stilbœstrol is the same as that of the natural œstrogens, in that it can (1) induce a proliferation of the endometrium, (2) abolish deficiency manifestations of the climacteric, (3) stimulate the growth of a hypoplastic uterus, (4) abolish the pains of dysmenorrhœa, and (5) prevent or inhibit lactation (Buschbeck and Hausknecht 1939, Lindemann 1939).

Divergent views have been expressed with regard to the occurrence of secondary symptoms

Buschbeck and Hausknecht (1939) found variations in tolerance to the drug, some patients tolerating as much as 21 mg daily, and others experiencing lassitude and vomiting with small doses. Some women tolerated injections but not tablets, and vice versa Ehrhardt, Kramman, and Schäfer (1939) describe similar phenomena.

Although all authors agree about the similarity of the properties of stilbœstrol to those of the follicle hormone, emphasis is constantly laid on the yet unresolved question of dosage. We accordingly sought to ascertain :—

(1) The minimal dose necessary to produce proliferation in a resting or atrophic endometrium.

(2) The dose necessary to induce a hyper-proliferation (in the sense of glandular cystic hyperplasia)

(3) The doses necessary to prevent and to inhibit lactation in the puerperium.

At the same time we sought to ascertain the dose of corpus-luteum hormone (anhydro-oxyprogesterone) given by mouth necessary to produce the stage of transformation of the endometrium with subsequent menstruation.

Observations on Castrated Women

We investigated 9 women who had for various reasons (mostly menorrhagia) been castrated with X rays two or three years ago when they were over 45 One of them was a woman, aged 63, whose menopause had occurred thirteen years ago

In each woman three trial curettages were carried out: (1) before treatment, (2) after administration

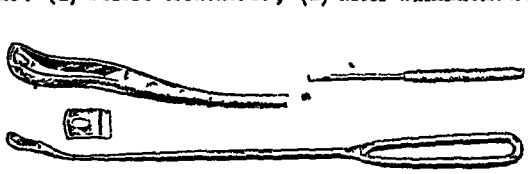

FIG. 1—Curette designed by Dr Karl Joël, showing interchangeable cutting edges

of stilbœstrol; and (3) after administration of anhydro-oxyprogesterone We wished by this means to determine histologically at each stage the effect on the endometrium. At the same time a portion of the material obtained was examined for its glycogen content.

We used a curette (fig. 1) designed by one of us (K. J.) and made by Laubscher and Co., Basle. It has the advantage that it can easily be introduced, after passing a sound, without dilatation of the cervix and has exchangeable cutting edges and is therefore always freshly sharpened.

ILLUSTRATIVE CASES

The following is a brief account of 2 of the 9 cases investigated.

CASE 1.—The patient, aged 54, had been castrated with X rays in 1937 because of climacteric hæmorrhages She had leucoplakia and vulval pruritus and kraurosis, with intense pain She was not curetted at the start of treatment. She was given stilbœstrol 10 mg (two tablets of 5 mg.) on Feb 17, 20, 23, 25, and 27, 1939, making a total dose of 50 mg. She was also given by mistake œstradiol (Ovocyclin) 5 mg. on March 1. On March 3 (the fifteenth day of the menstrual cycle) there was improvement as regards hot flushes, but the leucoplakia remained unchanged. She was curetted, a sound being passed a distance of 8 cm The ducts of the glands showed partial development of cysts of various sizes, the stroma was loosened, and occasional hæmorrhages were seen. No glycogen was found. Glandular cystic hyperplasia was diagnosed (fig. 2).

From the 3rd to the 12th she was given anhydro-oxyprogesterone 10 mg. (Lutocyclin, two tablets of

5 mg) daily, making a total dosage of 100 mg From the 12th to the 15th there was hæmorrhage On the 13th (the twenty-fifth day of the cycle) curettage showed the presence of glycogen and hæmorrhagic stroma—a stage partly of secretion and partly of glandular cystic hyperplasia

A second course of treatment followed, the patient receiving an intramuscular injection of stilbœstrol 3 mg on March 13, 17, 21, 24, and 27, making a total dosage of 15 mg Curettage on the 27th (the fourteenth day of the cycle), when a sound was passed for a distance of 9 cm , showed a stage of proliferation (fig 3), without any glycogen From March 28 to April 8 the patient received anhydro-oxyprogesterone 25 mg (five tablets of 5 mg) daily, making a total dosage of 300 mg From the 9th (the twenty-seventh day of the cycle) to the 13th there was fairly intense hæmorrhage Curettage on the 14th (the twenty-ninth day of the cycle), when a sound was passed for a distance of 8 5 cm , showed menstrual desquamation and hæmorrhages, and occasional glands showed alteration of secretion and the presence of glycogen

CASE 2 —The patient, aged 48, had been castrated with X rays in 1936 because of climacteric hæmorrhages On Feb 13, 1939, curettage, when a sound was passed for a distance of 7 cm , showed atrophy of the mucosa The patient was given stilbœstrol 5 mg (one tablet) on Feb 13 15, 18, 21, 23, 25, and 27, making a total dosage of 35 mg On the 28th (the sixteenth day of the cycle) there was some discharge Too little material was obtained by curettage for histological examination

From March 1 to 10 the patient was given anhydro-oxyprogesterone 10 mg (two tablets of 5 mg) daily, making a total dosage of 100 mg Curettage on the 11th (the twenty-eighth day of the cycle), when a sound was passed for a distance of 8 cm , showed a stage of transformation, with loose stroma and an abundance of vessels arranged typically There were definite deposits of glycogen in the epithelium and in the lumina of the glands There was no hæmorrhage

A second course of treatment followed, in which the patient received stilbœstrol 5 mg (one tablet) on the 11th, 14th 17th, 20th, and 23rd, making a total dosage of 25 mg Curettage on the 24th (the fifteenth day of the cycle) when a sound was passed for a distance of 10 cm , showed a stage of proliferation with the typical appearance of the glands and without glycogen

From March 25 to April 5 the patient was given anhydro-oxyprogesterone 25 mg (five 5 mg) daily, making a total of 300 mg

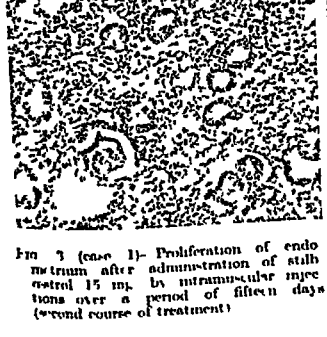

FIG 3 (case 1)—Proliferation of endometrium after administration of stilbœstrol 15 mg by intramuscular injections over a period of fifteen days (second course of treatment)

On April 2 (the twenty-fourth day of the cycle), after she had received altogether 220 mg of anhydro-oxyprogesterone, hæmorrhage appeared and continued until the 6th (the twenty-eighth day of the cycle), when curettage (a sound being passed for a distance of 10 cm) showed a stage of transformation, with abundant glycogen and with longitudinal extension of the glands (fig 4) On the same day the hæmorrhage ceased, except for a slight amount which continued until the 10th

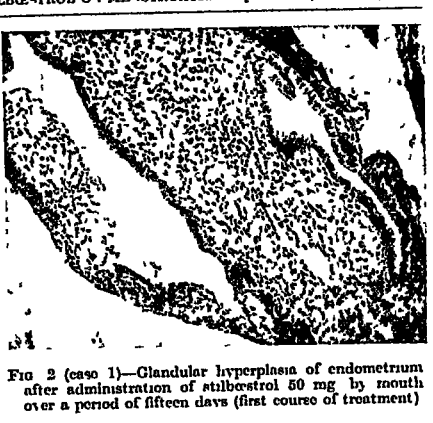

FIG 2 (case 1)—Glandular hyperplasia of endometrium after administration of stilbœstrol 50 mg by mouth over a period of fifteen days (first course of treatment)

EFFECTS OF STILBŒSTROL

At first our doses of stilbœstrol were too high We were led into this error by the high dosage of the tablets and by earlier experience with follicle hormone, which is less efficacious by mouth in a proportion of about 1 5 (Zondek 1929) With 50 mg we produced on three occasions a glandular cystic hyperplasia, which was histologically demonstrated In two other cases, in which 50 and 60 mg were given, curettage could not be performed owing to the illness of the women (influenza epidemic), and we cannot therefore say anything with certainty about the condition of the endometrium. On the basis of this experience we gave a second course of treatment to five women and produced a stage of proliferation with a dose of 25 mg —i e , with five tablets of 5 mg We may accordingly infer that the necessary dose for bringing an atrophic or a resting endometrium to the stage of proliferation is 25 mg of stilbœstrol in tablet form A dose of 50–60 mg will probably produce a glandular cystic hyperplasia By intramuscular injection 15 mg is sufficient, as we demonstrated in two cases

Besides the effect on the endometrium an effect on the myometrium was also demonstrated, similar to that already described by others (Buschbeck and Hausknecht 1930 Winterton and MacGregor 1939, Ehrhardt et al 1939 Bishop et al 1939) In all our cases an increase of 1–1 5 cm in the distance for which a sound could be passed was observed after the administration of stilbœstrol

Headache hot flushes pruritus vulvæ slight leucopl kia, and in one case neuritis were strikingly mitigated Only in two cases did the patient complain of fatigue general weakness, and nausea In one case there was vomiting These secondary symptoms were however, only fleeting and disappeared after a few days The women have remained under our observation up to the present time and have had no return of the trouble

EFFECTS OF ANHYDRO OXYPROGESTERONE

Anhydro oxyprogesterone was given by mouth after a stage of proliferation of the endometrium had

been produced with stilbœstrol. After using too little doses at first through lack of experience, we were able, by gradual increases, to ascertain the amount necessary to produce the stage of transformation with accompanying menstruation We gave at first 50–60 and 100 mg in two cases in which too much stilbœstrol had previously been administered. In these two cases, after this relatively small quantity

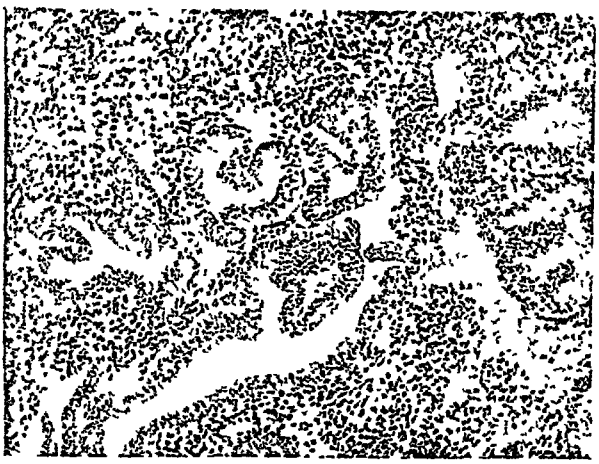

FIG 4 (case 2)—Transformation of the endometrium after administration of anhydro-oxyprogesterone 300 mg by mouth over a period of twelve days (second course of treatment)

of anhydro-oxyprogesterone, a hæmorrhage appeared. Examination of the endometrium, however, showed that there was a partial transformation and a slight amount of glycogen present, with glandular hyperplasia In two cases in which too much stilbœstrol had not been given no hæmorrhage appeared. Only in the case of the patient aged 63 was a hæmorrhage, which we must describe as menstruation, produced with 90 mg. We obtained genuine menstruation after complete transformation of the endometrium and with a positive glycogen content with 200 mg once, 220 mg. twice, and 300 mg twice On the strength of these five cases, confirmed histologically, we may infer that the dose of anhydro-oxyprogesterone by mouth necessary for the transformation lies between 220 and 300 mg. The case in which a menstrual hæmorrhage appeared after 90 mg we must regard as exceptional, and we must also assume that individual fluctuations will always appear.

We accordingly recommend that a dose of 300 mg by mouth should be considered as the transformation dose. When we compare this dose with that which is required in the case of injection of corpus-luteum hormone, which amounts to 40–50 mg. (Zondek 1935) or 60 mg (Clauberg and Uestün 1938), we have a proportion of 1·5 to 1 8 Oral medication has several advantages and was always tolerated without the production of any secondary symptoms, even in elderly women taking five tablets daily.

These doses of stilbœstrol and anhydro-oxyprogesterone must be regarded as maximal doses, for all our experiments were made on castrated women with an atrophic endometrium It is therefore possible, in the case of a resting endometrium, to produce a true menstruation with 25 mg. of stilbœstrol and 300 mg. of anhydro-oxyprogesterone by mouth.

Effects of Stilbœstrol on Lactation

Published reports have made it clear that the administration of the follicular hormone during the puerperium inhibits lactation. The mechanism of this action is explained thus. the follicle hormone prevents the secretion by the anterior lobe of the hypophysis of lactotrophic hormone, which normally first appears in the puerperium Several authors have succeeded, with various doses of follicle hormone (5–25 mg), in either preventing the influx of milk or inhibiting lactation which had already begun In the light of these observations we used stilbœstrol for the same purpose.

In 6 cases stilbœstrol was administered on the first day after confinement to prevent the secretion of milk These cases comprised 4 stillbirths, 1 tuberculous patient forbidden to suckle, and 1 multipara with depressed nipples who had never been able to suckle In 3 cases stilbœstrol 5 mg (one tablet) was given in the first twenty-four hours after confinement, in the 3 others 10 mg (two tablets) was given in one dose In all cases the treatment was successful, no milk was secreted, and the breasts remained flaccid

In 14 cases stilbœstrol was given to inhibit established lactation. The indications were hypogalactia, bleeding fissures, mastitis, eczema of the breasts, and tuberculosis. In 6 of these cases only 5 mg. (one tablet) was given, and the secretion of milk was completely arrested. In 2 of the women, however, the breasts were already flaccid and the secretion very meagre; the result must therefore be judged with caution. In 4 cases 10 mg (two tablets) was given in one dose with good results In 2 other cases the secretion of milk was arrested after the administration of 5 mg (one tablet), but after one or two days the breasts again became somewhat distended, whereupon another 5 mg. (one tablet) was administered, and the milk secretion was finally arrested, the breasts remaining flaccid In the remaining 2 cases the result was not so striking. In the first it was not possible to arrest the secretion of milk with 10 mg by mouth, and it ceased only after the additional intramuscular injection of œstradiol dipropionate 10 mg (ovocyclin P) In the second case the secretion decreased after the administration of 10 mg. but did not entirely cease. Complete inhibition was obtained after the administration of a further 5 mg. by mouth All the women took stilbœstrol without difficulty, and no secondary symptoms were observed

Our results show that the oral administration of stilbœstrol can prevent or arrest lactation. Doses of 5–10 mg. are sufficient, if given immediately after confinement, to prevent the secretion of milk with the greatest certainty. There is no need either to bind the breasts or to give aperients, and the pain from distension, which may be so distressing, does not occur For arresting lactation which has already set in 5–10 mg. is also sufficient in most cases, though in some cases larger doses were necessary (not more than 20 mg) The results are also very good, though not so striking and certain as in the prevention of lactation

From the foregoing considerations it is clear that stilbœstrol is a cheap substitute for follicle hormone, which is particularly efficacious when given by mouth and appears to be indicated for the prevention and inhibition of lactation

Summary

(1) The effect of stilbœstrol and anhydro oxyprogesterone on a patient who had attained the climacteric thirteen years earlier and on 8 women castrated by X rays was studied, and the state of the endometrium was determined by curettage.

(2) For the proliferation of a resting or atrophic endometrium stilbœstrol 25 mg by mouth or 15 mg injected intramuscularly is required

(3) With stilbœstrol 50–60 mg given by mouth a glandular cystic hyperplasia can be produced

(4) The stage of transformation and the menstruation following proliferation can be produced with anhydro oxyprogesterone 220–300 mg given by mouth

(5) Only in 2 cases were slight secondary symptoms observed after the administration of stilbœstrol, but these rapidly disappeared No secondary symptoms appeared after the administration of anhydro-oxyprogesterone in doses of 25 mg (five tablets) daily

(6) Lactation was either prevented or inhibited in 20 women by the administration of stilbœstrol 5–15 mg by mouth In most cases 5 mg was sufficient

We are indebted to Prof Werthemann and Dr Scheidegger, of the Pathological Anatomical Institute of Basle, for making the histological preparations, and to the Society of Chemical Industry in Basle (Ciba) and to the firm of Merck in Darmstadt for supplying us with their preparations

CLINICAL NOTES

INTUSSUSCEPTION OF THE APPENDIX

A REPORT OF TWO CASES

BY CECIL P G WAKELEY, D Sc Lond, F R C S, F R S E, F A C S, F R A C S

SENIOR SURGEON TO KING'S COLLEGE HOSPITAL, SURGEON TO THE BELGRAVE HOSPITAL FOR CHILDREN

ALTHOUGH intussusception of the appendix is well known, less than a hundred cases have been reported, but probably the incidence is greater than this would lead us to believe, for there must be many that come to operation and are not reported

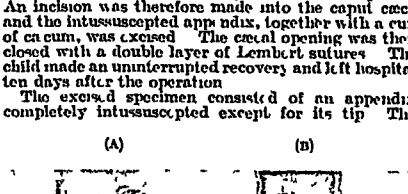
My first case was in 1919 and my second in 1938, an interval of twenty years Both patients were children, and it is interesting to note that most of the recorded cases have been in young children It seems probable that the same factors may be at work in the causation of intussusception of the appendix as are responsible for the enterocolic intussusception in infants The most constant feature in these cases is the presence of enlarged glands in the root of the mesentery and in the ileocæcal angle Also, there is a preponderance of lymphoid tissue in the terminal ileum and in the appendix This increased lymphoid tissue acts as a foreign body and causes increased and irregular peristalsis of the bowel and appendix, which at times culminates in an intussusception But this cannot always be the cause for the condition has been seen in children up to the age of 10 and even in adults, Huddy (1927) records a case in a man aged 39 Sometimes a stercolith may be an exciting cause of the intussusception, and worms may play a part

The histories of my two cases were as follows

CASE 1.—A boy, aged 10 months, was admitted to hospital in June, 1919, because of screaming attacks and diarrhœa of some two days duration The child was well nourished and apparently contented He allowed his abdomen to be palpated And finite lump was felt in the right iliac fossa, and manipulation of it caused him to scream The temperature was 100° F and the pulse rate 120

Acute appendicitis was diagnosed and the abdomen opened under gas-and-oxygen anæsthesia through a muscle-split incision in the right iliac fossa When the peritoneal cavity was opened, the cæcum was found to be hard, and, when this was delivered into the wound, only the tip of the appendix could be seen, the rest of it being invaginated into the cæcum (see figure) The terminal ileum was pulled downwards towards the tip of the appendix by the œdematous meso appendix An attempt to reduce the intussusception of the appendix was unsuccessful, for the peritoneal coat of the cæcum gave way in two places An incision was therefore made into the caput cæci, and the intussuscepted appendix, together with a cuff of cæcum, was excised The cæcal opening was then closed with a double layer of Lembert sutures The child made an uninterrupted recovery and left hospital ten days after the operation

The excised specimen consisted of an appendix completely intussuscepted except for its tip The



Intussusception of the appendix (A) external aspect, (B) on section The terminal ileum is pulled down by the œdematous meso-appendix

coats of the appendix were œdematous and infiltrated with blood, and the vessels in the meso appendix were thrombosed

CASE 2.—A boy aged 5 years, was admitted to hospital in December, 1938 with diarrhœa and vomiting of four days' duration The day before operation the doctor who was attending him noticed some blood and mucus in the stools and therefore suspected intussusception and recommended hospital treatment

On examination the boy appeared anxious and was considerably dehydrated, having vomited several times the night before admission On abdominal palpation a tender swelling could be felt in the right iliac fossa Notwithstanding its tenderness it could be moved about the iliac fossa, and the question of

appendix abscess was therefore dismissed and colic intussusception diagnosed. Rectal examination gave a negative result. The pulse-rate was 100 and the temperature 100 6° F.

Operation was performed through a right paramedian incision, and the cæcum and terminal ileum were delivered through the wound. An intussusception of the appendix was discovered and was with difficulty reduced and the appendix excised, the stump being buried in the cæcum. The boy made an uninterrupted recovery and was discharged twelve days after the operation. The appendix was œdematous and its wall in places necrotic, and the vessels in the meso-appendix were thrombosed.

It is nearly a hundred years ago that McKidd reported a case, and it seems difficult to believe that fewer than a hundred have been reported since.

DIFFUSE SCLERODERMA AND RAYNAUD'S PHENOMENON

FROM THE USE OF A PNEUMATIC HAMMER

BY DUNCAN LEYS, D M. Oxfd, M R C P
PHYSICIAN, ROYAL NORTHERN INFIRMARY, INVERNESS

IN 1924, when he was 42, the patient, a foreman mason, first noticed numbness of the fingers of both hands during cold weather He was then working in the United States, and had begun to use a compressed-air hammer the previous year The instrument was held in the right hand and a chisel in the left He continued to use the tool until 1930. Many of his mates had noticed similar symptoms and were annoyed by them, but nobody regarded the condition very seriously. When he returned to Scotland in 1934 he went on working as a mason, but not with a compressed-air tool. His hands still worried him in cold weather, but he noticed no other disability, except that the skin of the hands appeared to be getting thick, and there was some stiffness of the hands, which made flexion and extension of the fingers difficult In January, 1939, he had a fall on the ice when he was watching some curling, and about a week later he found that the numbness of the fingers in the left hand was worse, and that the grip seemed weak.

Examination.—Now 57 years of age, he was a man of middle size with a high colour. The face was expressionless and immobile and the mouth small The skin over the forehead and cheekbones and round about the mouth was tense, thin, and inelastic. With the utmost effort to open his mouth, the vertical aperture was not more than 1¼ in The palpebral fissures of both eyes were small. There was diffuse thickening of the subcutaneous tissues in both hands, extending down the fingers, across the palm, and over the dorsum of the hand, which prevented closure of the fist and full extension of the hand

All the fingers of both hands were pale. Lewis's hyperæmia test showed an abrupt cessation of flushing at the base of the palm and at the base of all five fingers on the dorsal aspect in both hands. Radial-artery pulsation was easily felt at the wrist in both hands The blood-pressure in the right arm was 130/70; in the left arm the systolic pressure was 110, but no diastolic end-point could be obtained. All the fingernails and the toenails to a less degree showed a convexity in a longitudinal direction; there was moderate clubbing of all the fingers. The peripheral arteries in the legs (dorsalis pedis and posterior tibial) could not be felt. The tendon jerks were present in the arms and legs and there was no evidence of any sensory disturbance, nor of muscle weakness The serum Wassermann reaction was negative. Radiograms of the hands showed slight "tufting" of the terminal phalanges only.

DISCUSSION

Scleroderma and Raynaud's phenomenon are commonly associated, and Raynaud's phenomenon is an occasional sequel to the use of pneumatic tools; but I can find no previous record of the two conditions developing together in a pneumatic-tool worker. The incidence of Raynaud's phenomenon in these trades is so high that individual susceptibility can play little part in its causation To the vibration itself (aided by cold) one must ascribe the permanent changes produced in the vessels. Loriga (1929) says that permanent changes in the vessels resulting from the use of compressed-air tools are unknown, but this is not generally agreed, and Hunt (1936) finds no complete recovery from the Raynaud condition even when work is stopped for considerable periods In the present case the question arises whether vibrations caused the scleroderma as well as the partial ischæmia of the fingers, or would the patient have developed these if he had never worked vibratory machines? Whatever the answer to this particular question, legislation to regulate the use of vibrating tools now seems to be overdue. For most trades tools have been devised which minimise the vibratory effects, and no others should be permitted.

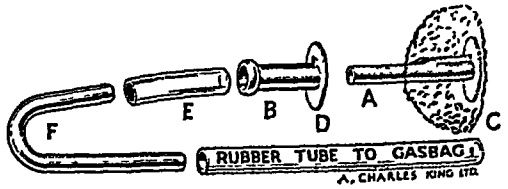
COMBINED SPONGE AND GAS-DELIVERY TUBE

I HAVE been using for the past few years the attachment illustrated here for prolonged administration of nasal gas for dental purposes. With this device gas is administered both through the throat sponge which is normally used by the dentist and through the nose by the orthodox nose-piece



The figure is self-explanatory. The sponge (C) is held between the collar on the male tube (A) and that on the female tube (B) The rubber junction tube (F) fits over tube (A) jamming tube (B) into place Induction is carried out in the ordinary way with a nose-piece. As soon as the patient is adequately anæsthetised, the damped sponge, ready mounted on the fitting and connected by rubber tubing to the gas apparatus, is pushed over the tongue and into the pharynx It is then immaterial whether the patient breathes through the nose or mouth

Since I have used this method I have had no difficulty in keeping any patient quiet for an indefinite time once I have succeeded in getting him really anæsthetised.

The fitting was made for me by Messrs A. Charles King, 34 Devonshire Street, London, W.1

SECTION OF NEUROLOGY AND PSYCHIATRY

WITH DR C P SYMONDS (London) in the chair, this section discussed

Symptomatic Headache

Prof HENRY COHEN (Liverpool) suggested classifying the causes of pains in the head on an anatomical basis Headache is incapable of quantitative assessment, we are therefore dependent on the patient's description of its site, duration character, and intensity Hence the patient's account of headache is often of little diagnostic value Only a small number of those suffering from headache were victims of intracranial disease Headache is the dominant symptom in "expanding lesions," meningeal irritation and diseases of the cerebral arteries In adults, the more rapid the development and the earlier and more severe the interference with the circulation of the cerebrospinal fluid, the more intense is the associated headache The dull, throbbing or bursting, splitting pain, aggravated by coughing, stooping, or straining, is associated with "expanding lesions" Pain beginning in the back of the head and radiating to the temples and frontal regions, accompanied by nuchal rigidity, is associated with meningeal irritation The migrainous type of pain is commonest in vascular lesions Yet all these types of headache have occurred in the absence of demonstrable cerebral pathology, suggesting that the essential mechanisms are functional and not dependent on an irreversible structural change Intracranial origin is suggested not by a description of the headache but by associated signs and symptoms The main factor in the mechanism of the pain is cerebral anoxia, benefit is frequently derived from the administration of oxygen

DR DESMOND CURRAN (London) said that the diagnosis of functional headaches, which were now recognised to be so common, was apt only to be reached by a process of exclusion, on the principle that it was first necessary to eliminate all possible physical causes The ruthless application of this principle could have the most unfortunate consequences, positive features should supplement the negative approach to the diagnosis

The fallacies inherent in the classical antithesis between "functional" and "organic" might lead to the erroneous conclusion that a psychiatric problem was synonymous with a psychogenic problem The head was not only something which was physically experienced but it was also something psychologically experienced as the place where our *ego is localised* It was therefore easy to understand how any threat to the ego or personality was experienced subjectively as a head discomfort or a headache, and hence why head discomforts or headache should be such a frequent symptom in mental disorder

The characteristic thing about a "functional" headache was its quality of closeness to as opposed to remoteness from the personality; it was not so much a typically sensory perception as an unpleasant experience with a special personal significance This led to the rather special proprietory attitude of "my headache" The other characteristic features of the functional headache were the selective disturbance of function and its variability in accordance with psychological rather than physical events

Much help might also be obtained from the study of the past history and personality of the individual concerned, and the presence of other symptoms of some psychiatric syndrome

DR D W C NORTHFIELD (London) said that the characteristic headaches usually caused by expanding intracranial lesions were not always accompanied by increased intracranial pressure, the pressure might in fact be abnormally low The theory that headache was due to pressure on or tension of the dura mater could now be discarded There was, however, much to support the view that headache arose from *an abnormal state of tension in the walls of the* cerebral blood vessels Biologically, headache signified a perilous position of the brain Repeatedly paroxysmal headache in a previously healthy person usually indicated a lesion needing surgical intervention

Prof G W PICKERING (London) stated that only two qualities of pain could be distinguished, the first, a sharp pain, described as pricking if the stimulus was short or burning if prolonged, arose from stimulation of the skin, the second, a dull pain, arose from structures deep to the skin He agreed with Dr Northfield that headache in intracranial lesions arose from the disturbance of sensitive structures lying round the blood vessels when they dilated A similar mechanism operated in headache produced by injection of histamine and headache associated with pyrexia He disagreed with Professor Cohen's suggestion that headache was due to cerebral anoxia One type of headache, common in healthy subjects, arose from prolonged tension of the muscles and tendons overlying the skull, and could be cured by voluntary relaxation

Dr T A ROSS (London) thought that neurotic patients often spoke of having a headache when they meant that they had painful feelings Headaches which could not be distinguished in any clinical sense from those of organic origin were sometimes undoubtedly precipitated by psychological factors

Mr NORMAN DOTT (Edinburgh) said that he also thought the pain of headache of intracranial origin arose from disturbance of the blood vessel walls, in general toxæmias also the tone of the intracranial blood-vessels was probably changed He believed that psychogenic headache was just as true a pain as that with an organic origin Pain, after all, was only a matter of faith except when we experienced it ourselves Dr RICHARD LAGER (Exeter) pointed out that headache might arise from eye strain or refractive errors the correction of which by suitable glasses gave immediate relief This cause was often overlooked

Dr D R MACCALMAN (Aberdeen) said that patients complaining of psychogenic headache often described it as unbearable This quality of unbearableness referred not to the pain but to the psychological cause producing it Psychological headache was not relieved by analgesic drugs whereas most organic headaches were, similarly the former did not affect sleep, which was indeed benefited by it, whereas the latter interfered with sleep In making a differential diagnosis one should also consider whether the headache served a useful purpose—did it relieve the patient of responsibility or unpleasantness? Psychogenic headache was never a single symptom of neurosis and one should never make the diagnosis

in the absence of other positive signs of psychogenic illness

Prof HUGH CAIRNS (Oxford) pointed out that a raised intracranial pressure could be altered by, for instance, deep breathing; it was this distention which gave rise to pain He doubted the validity of Professor Cohen's theory of anoxia, for he thought this a rare state clinically. Functional headache was not a pain in the true sense of the word. A distinctive quality not so far mentioned was its long and continuous duration; a headache which was present for more than three to four weeks was of this type Occasional migrainous attacks were a common preliminary in aneurysms

Dr. MACDONALD CRITCHLEY (London) said that typical cases of migraine often began after the age of forty, while some of them were menopausal. Although, as Dr. Curran suggested, headache was frequent in neurotics because the head was the centre of the ego, at the same time such patients often centred their pain in the lumbar region Many physicians were apt to suggest that functional headache was not real pain but obsessive thinking about pain He disagreed, for pain could be produced hypnotically which gave rise to the same effects as organic pain Psychogenic pain was as much pain as toothache

Prof COHEN replying said that Professor Pickering, Dr Northfield and he disagreed mainly on the question of the actual underlying mechanism of headache. There were two alternatives, that the painful stimulus came from the actual blood-vessel wall, and that, as a result of stimulation, the calibre of the vessels changed leading in turn to alterations in blood-supply, the resulting anoxia causing pain There was no doubt that administration of oxygen cured a migrainous attack Headache in anæmia was also more easily explained on an anoxic basis

SECTION OF OTO-RHINO-LARYNGOLOGY

THIS section met on July 26, under the presidency of Mr. H. BELL TAWSE (Nottingham), to discuss

The Bronchoscopist and Bronchopulmonary Disease

Dr CHEVALIER L JACKSON (Philadelphia) began by sketching the history of peroral endoscopy Appreciation of this method of examination had rapidly increased lately; soon every town would have its endoscopists Careful training of the endoscopist was therefore urgent In developing the technique of bronchoscopy and skill in recognising endoscopic appearances, detection and removal of foreign bodies was valuable experience The bronchoscope could be used first to elucidate symptoms of respiratory disease, such as dyspnœa, which were not explained clinically, and secondly to decide about further treatment in already recognised abscesses, unresolved pneumonias and tumours. The oto-rhino-laryngologists had initiated the technique, but Scott-Pinchin, Morlock, and other physicians and thoracic surgeons had contributed to its development. Bronchoscopy was no rival to surgery Treatment would often be bronchoscopy plus surgery As for American clinics, in some the physicians, in others the surgeons conducted the operation; in others again there was perfect coöperation between the physician or surgeon and the specialist More intensive training and knowledge for the bronchoscopist would lead to a new sense of responsibility and justify the use of the terms broncho-œsophagologist and bronchologist. The specialist was not merely an "-oscopist" but an "-ologist"

In empyema which cannot normally be treated by bronchoscopy it is sometimes found that surgical failure is due to obstruction, removal of which by bronchoscopy is followed by recovery. Bronchoscopy after an operation for empyema may reveal multiple broncholiths which can be removed Post-operative atelectasis often cleared after bronchoscopic aspiration of viscid secretion. Overholt of Philadelphia was having this procedure carried out as a preventive in some operation cases

Mr EWEN MARTIN (Edinburgh) quoted a series of 240 cases of carcinoma of the lung from the Royal Infirmary, Edinburgh, of which not one was operable Deep X-ray therapy was employed, but 200 died. Greater coöperation between physician and bronchoscopist, he thought, would lead to earlier use of the bronchoscope, earlier treatment and better results. To enable him to carry this greater responsibility the bronchoscopist required better training This could be achieved only by organising bronchoscopic clinics, but this degree of specialisation would be provided only when the State supplied the means Special broncho-œsophageal departments should be established in general hospitals Further opportunity for training would be given if the Home Office endoscopy licence regulations were relaxed to permit the pupil to practise on dogs under the surveillance of the expert The endoscopist should give the initial and final diagnosis, and his opinion as to when cases should be referred to the thoracic surgeon should be considered.

Mr. V. E NEGUS (London), in paying tribute to his training in Philadelphia, insisted that his wish had been not to improve but to simplify the Chevalier Jackson technique. In this simplified Chevalier Jackson technique the surgeon worked single-handed The instruments were kept in formalin and inserted by the surgeon in a quiver by the table The patient's head was steadied in a rest modified from the Haslinger type The Jackson type of laryngoscope with twin obliquely set lamps was used Crouching was avoided by raising the table. The patient was immobilised by means of arm rests After painting the pharynx down to the pyriform fossa with cocaine, avertin and omnopon-scopolamine were the usual preparations for œsophagoscopy Local anæsthesia alone was suitable for bronchoscopy in adults Children required rectal paraldehyde

Mr E. J. GILROY GLASS (Nottingham) said that bronchoscopy was limited in pulmonary disease in the upper lobe, where direct vision was impossible In these cases an adjuvant to bronchoscopy was bronchography, by injection of radio-opaque oil In addition to its usefulness in defining the extent of disease, this method could demonstrate occlusion of a bronchiole and make earlier diagnosis and operation possible His experience was that injection under direct vision led to loss of lipiodol by coughing on the way from ward to the X-ray room. After anæsthetising the pharynx and larynx with one per cent cocaine or a substitute, a 16 French gauge catheter was passed by direct laryngoscopy for 3 inches inside the trachea The catheter was then anchored by plaster to the cheek and the patient sent to the X-ray room There, with the guidance of the fluoro-cent screen, the radio-opaque, malleable and lead-tipped catheter was introduced into the required position For the lower lobes the erect position, and for the upper lobes the prone position with the opposite shoulder raised, was adopted By doubling the standard penetration, and in thick chests the standard

time of exposure, lesions invisible to ordinary exposure were revealed

Mr H BELL TAWSE wished to underline three themes from the discussion There must be collaboration between the laryngologist and physician and surgeon The voluntary and municipal hospitals must pool their resources and clinical material In the Nottingham endoscopic clinics more and more cases were being treated Thirdly, the surgeon doing thoracic work alone could only operate in this country in London and a few of the larger towns But even in smaller towns he felt that the oto rhino laryngologist must prepare for the arrival of the thoracic surgeon He recommended that a monthly animal endoscopy assistant's licence should be granted which could be used under the direction of the chief

Mr C A SCOTT RIDOUT (Portsmouth) said that special training should be facilitated by permission to work on dogs He himself was occasionally called on to remove foreign bodies from a dog's œsophagus

Mr P R ALLISON (Leeds) said that unless a "time" endoscopist could be always available, the surgeon must do his own endoscopy He quoted three cases (1) A man of 32 with a miner's cough which was found to be due to a bronchial carcinoma (2) A woman of 54 who was examined 3 weeks after "some toffee went the wrong way", the left lower lobe bronchus was found to be obstructed by granular tissue above an oat cell carcinoma for which pneumonectomy was performed (3) A suspected case of tuberculosis in which the bronchoscope showed only congested thickened mucosa, suction was applied through a curved catheter and malignant epithelium was removed, pneumonectomy was successful He said that 90 per cent of bronchial carcinomata were inoperable even if diagnosed relatively early

Mr I SIMSON HALL (Edinburgh) advocated preoperative bronchoscopic aspiration to prevent postoperative chest complications Mr T RITCHIE RODGER (Hull) favoured Mr Negus's head rest because it eliminated teamwork, which was impossible in small centres Dr DONALD WATSON (Bradford) concurred, Mr JAMES ADAM (Glasgow) liked preoperative aspiration and also postural drainage in bronchiectasis Mr I T I EDWARDS (Liverpool) said that whether bronchoscopy should be done by the oto rhino laryngologist or the thoracic surgeon depended on what the surgeon wanted to know No picture was so complete as the one seen by oneself The surgeon would want to see the lesion he was expected to remove Hæmoptysis in patients over 40 was serious and bronchoscopy must be done early as the margin between the operable and inoperable condition was one of only a few weeks Dr H A MCCOY (Adelaide) pointed out the difficulty of exactly defining the size of a tumour because the X ray shadow was partly due to collapse of the surrounding lung The question of treatment was therefore difficult to decide Before X ray therapy was condemned the exact dosage measurement achieved in the Holt Institute in Manchester should be considered Maximum doses should be used and the size and position of the tumour should be accurately known

Dr CHEVALIER JACKSON in reply supported the suggestion of endoscopic clinics in which specialists would treat the larynx as well as the œsophagus and bronchus The thoracic surgeon and physician should not be discouraged from doing endoscopy He commended the use of bronchography and quoted a case of pharyngeal paralysis in which a hazy shadow on a good film near the aorta on the left side was shown up more clearly by lipiodol injection, and later confirmed as a carcinoma He believed that postural drainage was more effective after bronchoscopic aspiration He had seen a pulmonary abscess cured by this means, which had also been useful in the treatment and even prevention of asthmatic attacks He agreed that the surgeon should see the lesion himself, but bronchoscopy only showed the upper edge of the tumour Exploratory thoracotomy should follow X ray of the chest and search for metastases in the bones, pleura, &c Deep X rays had been tried by Prendergast and all the Philadelphia radiologists without success in proved cancer cases So-called successes were cases of adenoma Tomography was being tried in chest as well as in larynx cases

Mr LWART MARTIN said he did not like Mr Negus's head-rest, but he favoured a clinic, run by a team of physician, surgeon and bronchoscopist working together He thought the surgeon should see the tumour he was expected to remove but need not become a bronchoscopist to deal with every case of hæmoptysis Postural drainage was ineffective without bronchoscopy and dilatation

Mr NEGUS replied that the failure of postural drainage in bronchiectasis was often due to occluding granulations in the mucosa above the cavity These could be shrunk at bronchoscopy, and the prolonged drainage effected gave relief for two or three months If obstruction was due to carcinomatous infiltration with collapse, bronchoscopy would allow expansion and accurate definition of the tumour by X rays

SECTION OF RADIOLOGY

AT a meeting of this section with Dr RUSSELL REYNOLDS (London) in the chair, a paper on

Radiosensitive Tumours

was read by Mr J RALSTON PATERSON (Manchester) He suggested that all tumours can be graded into three groups according to their response to radiation which is as characteristic as the morphology of the group The first group consists of radio resistant tumours arising from the fixed connective tissue elements of the body and including osteogenic sarcoma, chondrosarcoma, myogenic, neurogenic and fibrosarcoma, liposarcoma and melanoma The second includes tumours of limited sensitivity which are curable by radiation only if of small size and then only by heavy dosage Squamous carcinoma transitional and basal cell carcinomata and adenocarcinoma of columnar cell origin belong to this group The third group is made up of highly sensitive types and contains, apart from certain well known and already accepted embryonal tumours of the testis and ovary, a large number of tumours derived from primitive mesenchyme and originating in the hæmopoietic, lymphatic, reticular and endothelial systems which Mr Paterson calls the reticulo endothelial neoplasias An extended but not exclusive list of these conditions is as follows —

Lymphosarcoma
Lymphadenoma
Leukæmia—
Myeloge nous
Lymphath
Erythroerythæmia
Ewing, a tumour (endothelial myel oma)
Endothelioma of vascular origin—
Hæmangioendothelioma
Angiosarcoma
Multiple reticuloses —
(a) of lymphoid tissue
Lymphoma
Lymphon atosis
Lymphoblastoma follicul'are
Multiple reticuloses (*cont*) —
(b) of stromate reticulum
Malignant Christian disease
Hand-Schüller-Christian disease
Niemann-Pick disease
(c) of marrow reticulum
Multiple myeloma
Plasmacytoma
Chloroma
(d) of mesenchymal angioconnective tissue
Multiple sarcoids (Boeck's sarcoid)
Mycosis fungoides
Retinal sarcoma
Subcutaneous lymphadenomata.

It is not possible said Mr Paterson to delineate many of these tumours pathologically; the names

are landmarks between which there is no real line of demarcation. As an example, the name lymphosarcoma had been used to indicate tumours of lymphocytes and tumours of reticulum cells, and further confusion has been introduced by the controversy as to which is the primitive stem cell, the lymphocyte or the reticulum cell of the germinal centre. Lymphadenoma shows a wider range of individual sensitivity extending from the highly sensitive malignant Hodgkin's disease to the localised nodes, where the lymphoid structure is almost completely replaced by fibrous tissue and is relatively resistant. According to Ewing, the tumour which bears his name takes on three forms—angio-endothelioma, reticular myeloma and diffuse myeloma. Angio-endothelioma is the best term to cover tumours derived from primitive angioblasts and these have a wide range of malignancy yet are all radiosensitive. Tumours of the pleura, peritoneum and synovial linings are not sensitive and must be regarded as of the same type as the other fixed connective-tissue tumours. Multiple reticulosis is a wide term. The lymphoid types are closely associated on the one hand with lymphatic leukæmia and on the other with lymphosarcoma and lymphadenoma. Of the bone-marrow reticuloses, multiple myeloma is ordinarily regarded as an entity apart from Ewing's tumour.

Sensitive tumours are also found in the nasopharynx and nasal sinuses, the salivary and lacrimal glands, and in the thyroid, thymus and kidney. Mr. Paterson suggested that although these tumours may be embryonal they may well be included under the term reticulo-endothelial neoplasias since they develop in sites of complex embryonic development and some are clearly of recognised reticulo-endothelial origin. When the widespread nature of the reticulo-endothelial neoplasias is realised and their general sensitivity accepted, it is only necessary to relegate an individual tumour to this group to develop a line of approach to treatment irrespective of its exact variety. Where there is doubt as to the nature of the tumour a sensitivity test should be performed, which consists of treating a single nodule or lymphatic node, or of using a field limited to a palpable tumour, and giving a dose large enough to make any sensitive tumour show some response quite rapidly and yet not too large to prejudice subsequent treatment. It is not possible to fix a lethal dose of X radiation for each tumour of this group; while at the upper limit 4000 r in three weeks will cure the great proportion of them, at the lower limit few fail to recur after doses of less than 1000 r administered within a week or two in spite of a spectacular initial response. In general, large fields are necessary, and with such a dose systemic tolerance would not be exceeded.

The generalised reticuloses call for even wider treatment, and the sensitivity may be so great as to bring about disappearance of the tumour completely with doses of 1000 r in three to six weeks. Permanent cure is, however, rare. Mr. Paterson does not regard whole body irradiation as a practical method of treatment, since even with the most sensitive of these tumours the chance of a lethal effect is slight within the limits of tolerance. He concluded that many localised tumours of this class can be cured by full dosage and that their notoriously bad prognosis is often associated with inadequate treatment masked by a spectacular immediate response.

The CHAIRMAN supported Mr. Paterson's suggestion that both pathological and radiological interests would be well served if a registry of the diseases of the reticulo-endothelial system were formed similar to the American registry of bone sarcoma.

Thorotrast in the Diagnosis of Cerebral Lesions

Mr. ROBERT MCWHIRTER (Edinburgh) said that there are cases where after clinical examination, routine radiography and ventriculography, the nature and localisation of the lesion can only be demonstrated by the use of Thorotrast. It may be injected into the blood-vessels (arteriography), into cystic cavities, or into the ventricles. He laid stress on the value of stereography although two injections may then be required because of the rapidity with which the arterial shadow becomes obscured by that of the veins.

In the case of saccular aneurysms of the major basal arteries, while the syndrome is typical, the line of surgical treatment depends on recognition of the exact site. If the aneurysm is below the bifurcation of the internal carotid it can be treated by ligation in the neck but if above direct operative attack is necessary. Both sides of the cerebral circulation may require injection. Arteriography can also differentiate an aneurysm from hæmorrhage in a tumour or from tumours invading the cavernous sinus which may give an identical clinical picture. Arteriovenous aneurysms may cause irritative or paretic symptoms without rise in intracranial pressure. With arteriography they appear as dense irregular shadows and the feeding artery may be so visualised that ligation is possible. Failing this the condition responds well to X radiation. Tumours may distort the normal arterial relations. This sign is of particular value when the first part of the internal carotid within the skull is displaced but superficial tumours, such as post-traumatic subdural hæmatomas, may also be localised in this way. In certain tumours, particularly glioblastoma multiforme, the vascular channels of the tumour may be visualised as large irregular sinusoids, and both its site and nature demonstrated. Mr. McWhirter had found arteriography useful in distinguishing the nature of the vessels in a case of cirsoid aneurysm of the scalp. Where lateral-sinus thrombosis is suspected injection of thorotrast through a burr hole over the longitudinal sinus will indicate that thrombosis has taken place by a failure of the sinus to fill.

Often in preliminary cerebral exploration cystic cavities are found and the injection of a few cubic centimetres of thorotrast into them will enable their nature and extent to be determined. Radiography is performed three or four days later when the thorotrast is flocculated on the cyst walls. The cysts associated with simple tumours have smooth walls and the tumour may be shown projecting into one side, whereas cysts formed within malignant tumours are rough and irregular. Injection of thorotrast into the ventricular system is rarely necessary, but when the third ventricle or aqueduct is narrowed it is difficult to get air into these structures and a fluid medium then gives better results. At the time of operation the thorotrast must be washed out with Ringer's solution as completely as possible.

In conclusion Mr. McWhirter discussed the dangers that may follow thorotrast injections. In arteriography the amount used is small in relation to the lethal dose. In cystic cavities it cannot be of any real danger. When injected into the ventricles it can be washed out again, and in the few cases he has examined in this way there has been no evidence of damage over periods as long as four years after the examination.

Dr. S. COCHRANE SHANKS (*London*) commented on the high position of the straight sinus as shown in many of Mr. McWhirter's illustrations. He mentioned the danger of ependymitis following the injection of thorotrast into the ventricles and asked whether any other substance is available for this type of work.

Dr D S RUSSELL (London) said that the effect of thorotrast on the vascular system is negligible It is ultimately stored in the cells of the reticulo endothelial system When a tumour is present in the brain, however, her experimental work had shown that small vessels about the tumour are occluded, the symptoms are aggravated and recovery is slow She did not think intraventricular injection is ever justifiable since even washing cannot prevent some of the substance from remaining in the spaces of the leptomeninges, and the possibility of occlusion and of hydrocephalus later must be considered In animal experiments this has happened, and she had seen a septic meningitis follow within 24 hours in one case and diffuse ependymitis and fibroid meningitis in another

Dr A E BARCLAY (Oxford) said that other media have been tried for the purpose of arteriography Uroselectan intravenously has been found dangerous and abandoned, but Perabrodil in a 35 per cent solution in quantities of 5 c.cm gives a good shadow in arteriography, 50 per cent perabrodil may cause shock

The CHAIRMAN commented on the value of thorotrast in the outlining of aneurysm, and also in the cysts associated with tumours He agreed that the intraventricular injection of thorotrast is unjustifiable

In replying, Mr MCWHIRTER said that the straight sinus has a rather higher site than that generally indicated anatomically and thought this may be due to displacement when seen in the cadaver Stereoscopic films can be taken in 0·8 second with suitable teamwork and rehearsals He did not think that perabrodil would give sufficient contrast for this type of work Attempts now being made to combine iodine with benzene have not yet reached a practical stage Intraventricular thorotrast is rarely used and then only as the last means of obtaining necessary information The fatal dose of thorotrast is ten micrograms, in cerebral arteriography only an eightieth part of this amount is used

REVIEWS AND NOTICES OF BOOKS

Menstrual Disorders

Pathology, Diagnosis and Treatment By C FREDERIC FLUHMAN B.A., M.D., C.M., *associate* professor of obstetrics and gynecology, Stanford University school of medicine, San Francisco, California London W. B. Saunders Company 1939 Pp. 320 22*s.* 6*d.*

IT is only in the past two or three years that the fruits of the extensive post-war researches into the physiology of reproduction have begun to find their way fully into clinical literature Professor Fluhman's welcome book is an attempt "to set forth our present concepts of the physiology of the menstrual cycle in women, and the various disorders which may occur under the influence of local and systemic disease" Special emphasis has been laid on endocrinology, but without loss of the general view-point which confronts the practitioner Dr Fluhman is in a fortunate position for writing on this subject because, apart from many years of clinical experience, he has himself made several important contributions to the experimental investigation of the human menstrual cycle

The first half of the book deals with the physiology of the cycle, and the second, which will probably have a far wider appeal, with the pathology and treatment of menstrual disorders After a historical introduction, there is a discussion of puberty, in which mention is made of the seasonal onset of the menarche and the irregularity and usual sterility of the first menstrual cycles The growth and the cyclical changes of the uterus, vagina and ovaries are next dealt with, and the length of the menstrual cycle and the systemic changes which occur in relation to it are considered A brief account of the sex hormones leads on to a chapter on modern methods of investigation, these include techniques for the collection and examination of biopsy specimens of the endometrium, and tests for the various sex hormones in the urine and blood Dr Fluhman warns against the too ready interpretation of biopsy specimens because of the different histological pictures which are presented by different endometrial areas Unfortunately, the first of the two techniques which is advised for the assay of œstrogenic hormone is hardly likely to be found reliable, and will almost certainly prove misleading

The clinical half of the book opens with a chapter on the practical application of the sex hormones and the use of irradiation of the ovaries and hypophysis in the treatment of menstrual disorders The various menstrual and menopausal disorders are classified and lucidly discussed Dr Fluhman is not carried away by the promise of endocrine therapy, and maintains throughout a conservative attitude to the problems he discusses

The book is clearly written and well illustrated In general, too, it is sound, but in the physiological section Dr Fluhman sometimes subscribes with assurance to views, such as the constant formation of ova during adult life, which are by no means established Occasional half statements—for example, that uterine bleeding can occur during the course of œstrogenic stimulation—leave an incomplete and, in one or two places, misleading impression On the other hand, the discussion of such clinical questions as metropathia hæmorrhagica leaves little to be desired, and the book therefore deserves wide recognition among clinicians Experimental investigators of reproduction should also find it a useful storehouse of clinical problems, though it makes no pretence of being a textbook of reproductive physiology

Textbook of Medical Treatment

By Various Authors Edited by D. M. DUNLOP M.D., F.R.C.P.E., professor of therapeutics and clinical medicine, University of Edinburgh L. S. P. DAVIDSON M.D., F.R.C.P.E., M.R.C.P., professor of medicine, University of Edinburgh, and J. W. MCNEE, D.Sc., M.D., F.R.C.P., R.A.M.C. professor of the practice of medicine, University of Glasgow Edinburgh E. and S. Livingstone 1939 Pp. 1127 26*s.*

Of recent years new textbooks of treatment, especially from America, have been numerous Most of them claim to be modern in their outlook, critical yet constructive to dispense with the traditional "exhibition" of drugs whose power is a matter of faith more than of reason to be precise and explicit; to be up to date in respect of new and worth while methods, to use drugs intelligently, and to concern themselves as much with the management of the patient in the wider sense as with the specific therapy of his disease But the market is not so full that it cannot welcome another of the kind when it achieves these aims so fully and successfully as does this volume from the Scottish medical schools In size, form and arrangement it is a companion to the textbook of

medicine edited by J. J. Conybeare and also published by Messrs Livingstone. Its contributors are two dozen or more teachers from Edinburgh, Glasgow and Aberdeen It covers the usual range of medicine as taught in this country, together with sections on the commoner skin diseases, some tropical diseases, and some of the commoner diseases of infancy and childhood There is an excellent chapter by D. R MacCalman on psychotherapy in general practice, and a useful concluding section on technical procedures and oxygen therapy Most of its contributors have achieved a freshness of style and approach that makes the book entertaining as well as instructive to read Their matter is sound and their perspective sensible We heartily commend what Prof. A J Clark describes in his foreword as "a very practical account of the methods of rational therapeutics, of which a large proportion have been evolved during this century"

La chirurgie radicale du cancer de l'œsophage thoracique

By MICHEL BALLIVET, *ancien interne des hôpitaux de Lyon* Paris: Librairie Louis Arnette. 1939. Pp. 325 Frs 30.

In this thesis the author makes a thorough study of the present position of the surgery of cancer of the thoracic portion of the œsophagus The anatomical, physiological and surgical questions involved, the various methods of approach and the 24 successful operations which have so far been published are considered in detail Finally a careful description is given of three cases operated on by the author with his chief, Dr. Ricard, by the method of Torek All three of these patients died, two within 36 hours and one a week after operation. While this thesis contains nothing that is new, it collects together as the result of much painstaking work all that has been written to date on this difficult and somewhat disheartening subject.

Handbook of Bacteriology

(5th ed.) By JOSEPH W. BIGGER, M D., Sc.D. Dubl., F R C P.I., M.R.C.P., D.P.H., professor of bacteriology and preventive medicine, University of Dublin London: Baillière, Tindall and Cox. 1939. Pp. 466. 12*s*. 6*d*.

THIS new edition of a popular handbook has been brought up to date without losing any of its former appeal. The attractive style and the personal touch remain unchanged.

The chief new features are the chapters dealing with streptococci and chemotherapy The chapter on streptococci has been almost completely rewritten and contains much new matter, carefully chosen and concisely expounded Happily for the student and others, such terms as *Streptococcus longus* and *brevis*, alpha, beta and gamma hæmolysis are now omitted, while *Streptococcus viridans* and *Streptococcus scarlatinæ* are no longer described as separate entities. The only terms retained are hæmolytic and non-hæmolytic streptococci, the latter including *S salivarius* which produces a greenish discoloration on blood agar, and *S faecalis* which does not The author adds "this is certainly an unwarranted simplification of the true position, but for practical purposes it will suffice, until more general agreement has been reached as regards these organisms" The Lancefield groups are well described; the actual method of performing the precipitin tests, however, is not mentioned, and one wonders whether a short paragraph on this subject would not have been more useful to students and practitioners of the future than the somewhat detailed accounts, elsewhere in the book, of opsonic methods, phagocytosis and the standardisation of antitoxins.

In the chapter on chemotherapy the use of mandelic acid in urinary infections is now mentioned and a new paragraph on the uses of sulphanilamide drugs is included These drugs are also mentioned in connexion with the treatment of gonococcal, meningococcal, pneumococcal and streptococcal infections. Other additions are the description of tetrathionate broth and its uses in the isolation of *B. typhosum* from the stools The significance of the Vi titre in typhoid is stressed, *B paratyphosum* C has been added to the salmonella group, and staphylococcal enterotoxins are mentioned in connexion with food-poisoning Some modifications are introduced in the methods of concentration and culture of tubercle bacilli The tuberculin-patch test has been omitted, although this is now extensively used

In classification, the author has not invariably followed Bergey's lead in the "Manual of Determinative Bacteriology," sometimes preferring the more conservative nomenclature of Topley and Wilson Morax-Axenfeld's diplobacillus and Ducrey's bacillus are included in the genus hæmophilus with the bacilli of Koch-Weeks, influenza and whooping-cough In the chapter on technical methods, students and their teachers would perhaps have welcomed a description of Albert's staining method for *C diphtheriæ*, and of the modified method of gram staining as used by the American Society of Bacteriologists No reference is made in the chapter on blood-culture to the use of sodium polyanethol sulphonate or Liquoid Among the new illustrations are some photographs of viruses by Van Rooyen The plate representing the comparator box for determining the pH of media is less clear than in the old edition. Apart from the few omissions mentioned, the manual is very comprehensive and answers the definite purpose for which it has been written

Treatment of Rheumatism in General Practice

(3rd ed.). By W. S. C COPEMAN, M D. Camb., F.R C P., physician in charge, chronic rheumatic diseases, West London Hospital; physician to the British Red Cross Society Clinic for Rheumatism, Peto Place London: Edward Arnold and Co 1939. Pp 270. 10*s* 6*d*

THIS book is deservedly popular In the new edition chapters have been added on gout and some new methods of treatment Physical, orthopædic, and occupational therapy are fully and satisfactorily described. Throughout those arts which are based on the author's personal experience bear the stamp of close observation and practical judgment, but occasionally statements are quoted from the work of others which do not appear to have been put to the test or, in some instances at least, they would not have been mentioned The suggestions for diet in rheumatic diseases are useful but it is not obvious why vegetables and fruits liable to oxaluria should be prohibited in gout; they are indeed often beneficial, and spinach in particular was highly commended by Luff. There are more misprints than one would expect in a third edition, and a curious confusion seems to have arisen between guaiacum and guaiacol The author says he prescribed guaiacol in the form of the "Chelsea Pensioner", this however does not contain guaiacol but guaiacum, "tincture of guaiacol" will provide a puzzle for the pharmacist.

The book is written in a pleasant and interesting style and will be of real value to the practitioner.

THE LANCET

LONDON SATURDAY, SEPTEMBER 23, 1939

THE HOSPITAL SERVICES

"There is always a great waste of personnel in war You cannot provide for the average incidence of injury and disease You are either overwhelmed with work or you have nothing to do It all depends on that unknown factor, the enemy's mind Personally, I do not think we can make any real complaint about things at present They re bad, but not too bad I ve seen worse"

THESE words from a correspondent embody the long view The hospital services of this country, and especially of London, have been adapted overnight to take a new and different kind of strain, the Government's object—to secure 200,000 beds for casualties and some sort of staff and equipment for them—has been achieved, and if air-attack had already begun we should probably be regarding the arrangements as a triumph of organisation As it is, the state of the enemy's mind has provided a breathing-space in which to be critical and try to correct faults in the machinery So far as the emergency hospital services are concerned these faults, in ascending order of importance, are hardship to personnel, inefficiency of working, and neglect of the ordinary needs of the population

War breeds injustice everywhere, but we trust means can be found to rectify some of the inequalities of sacrifice demanded of the members of the Emergency Medical Service Almost all consultants in London have been mobilised, or on call, since the war began, and most of them have ceased all other work, but those who are merely "held in readiness" receive no pay, and some of those who (misreading ambiguous instructions) reported for duty at their allotted posts now learn that they will be expected to pay for their billets! The rates of remuneration are, perhaps inevitably, crude, housemen and former registrars have had their incomes suddenly raised beyond their dreams, while experienced men with heavy domestic obligations find themselves with salaries that will mean rapid (though not discreditable) bankruptcy Often they lose even more than those joining the fighting forces as juniors, for these at least have hope of promotion and of pensions for their widows Cannot marriage and family allowances and pension rights be provided in the EMS so as to reduce the penalties of dutiful citizenship? Meanwhile, consulting-room rents, insurance premiums educational fees, and income-tax demands will continue, and many consultants are asking whether they cannot take a day or two s leave each week, when circumstances permit, to keep together the nucleus of their practices If such permission were general it might be fair enough but we fear it would be wrong in principle Full time status should rule out part time practice Nor is the Ministry's offer of leave without pay generally acceptable, for consultants who have wound up their work for the time being will seldom wish to unwind it for what may be only a week or a month There is more to be said for the latest plan by which some of the senior men who prefer to return to private work will, if they wish, be released from full-time obligations, and will attend the hospitals as part-time consultants until their full services are needed

The efficiency of the new casualty service depends on its personnel and its equipment, and we are confident that it is capable of rising to any possible occasion Clearly, however, it would work more smoothly if there were some revision of the appointments made, since many people are being asked to undertake duties unnecessarily remote from those they normally perform, and great skill is sometimes harnessed to primitive tasks Both as regards equipment and economy of talent much advantage might be secured if the Ministry of Health would send commissioners to survey the whole service—starting perhaps with casualty-clearing stations and working outwards The commissioners should have power to correct anomalies, supply deficiencies, and give definite rulings, for in an organisation built hastily on a mixed foundation of local patriotism, bureaucracy, and the decisions of harassed sector officers, mortiсed by goodwill, there is necessarily much to amend Apart from official action of this kind, we believe it might be useful if the doctors in each sector or area formed a committee to canalise and present their many ideas for the betterment of the service

The neglect of everyday needs of the population has now been recognised as dangerous and hospitals in London are being encouraged to admit a few patients What is more important, however, is the reopening of outpatient departments and the return of some of the men who run special clinics —e g , for diabetics If London is attacked, outpatients must still be seen there, but whether it is attacked or not most inpatient treatment must now be undertaken in the country It is here that we come up against the difficulty that London patients cannot be admitted to the hospitals run by the authorities of other counties, and if this difficulty can be overcome in no other way it may be necessary to unify the entire hospital service under the direct control of the Ministry of Health Already the voluntary hospitals, willy nilly, are existing from week to week on the Ministry's cheques, and if municipal hospitals are to change in function and accept Government-paid staff they cannot preserve a local outlook, and their own institutions and officers may have to join the national service The past fortnight has seen the consultants of the London area sitting idle while patients in need of help have waited on the other side of inviolable barriers If circumstances have planted a first-class gynæcologist or orthopædic surgeon at a hospital outside London it seems folly not to let him, between air-raids use his talents for the benefit of the people round about. If the organisation for

this purpose does not exist, it must be improvised On another page Dr. HELEN MACKAY gives an excellent example of the sort of work pædiatricians might do among a population largely evacuated, and there is no lack of desire among any kind of consultants and practitioners to do their best in the station to which they have now unluckily been called. What they insistently demand is to be allowed contact with the patients they can help.

CAUSATION OF CARCINOMA OF THE BREAST

AN important experimental contribution to the ætiology of mammary cancer is made by GREENE in three papers [1] In 1929 he began to establish a colony of rabbits with the object of studying the incidence of neoplastic diseases among them One of the animals then purchased was a Belgian hare, which afterwards developed a cystic condition of the breast. As it was not possible to maintain the offspring of this animal by close inter-breeding, other strains of Belgian hares, and subsequently of English rabbits, were used for crossing. The English rabbits were later found to be a second source of breast tumours, which were however of a different type In the colony of rabbits thus formed a surprisingly large number of mammary tumours developed spontaneously. This is in itself interesting, because mammary tumours have hitherto been but rarely found in rabbits. It is well established that in every species of animal so far investigated the spontaneous development of cancer is focused on only one or two organs, and that these specially susceptible organs vary from species to species In the rabbit the most favoured site for neoplasia is the uterus

The mammary tumours developing in GREENE'S colony fell into two groups which could be distinguished clinically and morphologically Of 25 animals the development of neoplasia was preceded by a cystic disease of the mamma in 21, while in the remaining 4 no antecedent mammary change was observed Frequent biopsies of this material showed that this cystic condition clearly resembles that found in Schimmelbusch's disease in women. Thence it passes into a stage of non-invasive neoplasia, in which growths are found still within the normal boundaries but already possessing the abnormal cellular morphology associated with frankly malignant tumours Eventually this stage passes into the stage of invasion that characterises a fully developed mammary cancer. In the 4 animals in which the cancer did not supervene on cystic disease the malignant process was at first confined to a small number of acini, the resulting tumours showing an adenomatous structure Metastases were found in both groups of tumours, and in some animals were widespread. Of the numerous photomicrographs presented by GREENE many show a striking resemblance to those of human cancer reproduced by CHEATLE and CUTLER in their well-known book on Tumours of the Breast. In view of the constancy with which cystic disease and neoplasia succeeded each other in these rabbits GREENE concludes that they probably represent progressive stages of a pathological process

He finds further evidence of such a relationship in the fact that the endocrine system of his rabbits showed changes corresponding to those described by CRAMER and HORNING in inbred mice with a high incidence of mammary cancer and in mice in which mammary cancer had been induced by the long-continued application of œstrogens. Thus he observed extensive degenerative changes in and around the medulla of the suprarenal glands While these adrenal changes were found in association with both types of mammary tumours, changes in the pituitary were seen only in those rabbits in which neoplasia had been preceded by the cystic condition. In these animals the pituitary was greatly enlarged, the enlargement being almost wholly due to hyperplasia of the chromophobe cells of the anterior part, which in a few cases was so localised as to form an adenoma. These findings lend further support to the idea that a characteristic disturbance of the endocrine balance is concerned in the causation of the type of mammary cancer associated with an inherited susceptibility This should encourage clinical pathologists to examine more closely the endocrine organs in cases of mammary cancer, especially those with a family history of this form of carcinoma.

TREATING ANXIETY STATES

MORBID anxiety, like cloudy swelling, is present in most people at some time or other. Anxiety is probably the commonest psychological reaction to stress, and is a frequent accompaniment of organic disease, colouring and distorting the clinical picture. It is known that the autonomic disturbance associated with anxiety lowers the threshold of visceral and somatic sensibility, and this has often been used to explain the somatic symptoms of which these patients complain In a recent paper KERR and co-workers [1] have drawn attention to the need of a fuller understanding of these mechanisms and a broader approach to their treatment. It is recognised that the majority of cases of cardiospasm, pylorospasm and spastic colon have a basis of anxiety, and the authors point out that while drugs of the atropine group are valuable when excessive peristalsis gives discomfort, psychological investigation offers hope of an understanding of the nature of the disease and the possibility of a permanent recovery. It is a pity that most of the cases of anxiety state with somatic symptoms are treated either by suggestion and drugs which can act only by suggestion, or by sedatives such as bromide and phenobarbital, psychotherapeutic investigation being omitted for economic reasons or from lack of time The results of such palliative treatment are good, because the initial causative environmental stress passes with time, and a certain equilibration of psychic conflicts takes place But the fundamental maladjustment, the psycho-pathological process, remains unchanged The authors point out that despite

1. Kerr, W. J., Gliebe, P. A., Soley, M. H., and Shock, N. W., *J. Amer. med. Assoc* 1939, 113, 637

active treatment there will always remain a small group of "psychopathically and protoplasmically" inferior patients who are untreatable The danger would appear to be the tendency to include in this group many of those hypochondriacs whose symptoms have developed during the course of an untreated anxiety state which has lasted for years and in which the anxiety is now latent In the clinics and out-patient departments of this country will be found many such patients towards whom the doctor has developed an attitude of complacent nihilism This group constitutes a large proportion of the chronic neurotic population and is becoming a slur on psychiatry If it is vital to exclude the organic it is even more important to exclude it rapidly and finally, as the habit of recurrent test-meals, X rays and blood-counts, without coincident psychological investigation, produces the soil most fertile for hypochondria Again, hypochondria is encouraged in just those cases that are treated by suggestion and drugs alone, whether or not they recover, because in the latter event the patient's initial resistance to the psychological approach is reinforced by the conclusion that the original cause of his trouble must have been physical, since it was relieved by medicine

MEDICAL LIBRARIES IN WAR-TIME

FOR one reason or another the first fortnight of the war found three of the principal medical libraries closed, one with half its stock boarded up and inaccessible, one with three-quarters and another with the whole of its staff gone We trust that this does not represent the general policy to be followed, for as the work of the medical profession becomes greater, not less, in war-time than in peace, its need for information may be more, not less, urgent. In a long war the profession will need the most up to-date information that can be provided by well-equipped and efficiently managed libraries The chief requirements as we see them, are fourfold an adequate service for the loan of books and periodicals and the supply of information to the medical officer overseas, a similar service for the profession in this country, library facilities for medical students in the centres to which they have been transferred, if such are not already present, and the usual or rather enhanced, provision of material for the essential research that must be carried on

To coordinate all the sources of information a central bureau should be set up by some such body as the Ministry of Information or the Medical Research Council Any doctor wherever he is, who requires a book or piece of information for essential work, should be able to obtain it without formality and with the least possible delay through the agency of this central information bureau which in its turn should be able to draw upon the resources of all medical or scientific libraries able to produce the required book or information The present is no time for parochial considerations and all medical libraries whether belonging to government departments, university institutions or private societies, should coöperate to the fullest possible extent, relaxing if necessary some of their usual rules and restrictions If this entail, as it probably will, extra cost, and to private societies loss of revenue owing to the removal of any special privileges due to membership, this may have to be made good by government subsidy In time of war facilities should not be withheld merely because those requiring them do not happen to be members of the particular institution able to provide them This raises another question—that of skilled library staffs Medical libraries are of little if any use without librarians During the last war the library of the Royal Society of Medicine had such demands made upon it by the medical officers of our own and allied armies that it was found necessary to obtain exemption from military service for its expert staff The need this time, as we have indicated above, will be even greater, yet there is no mention of medical librarians in the Ministry of Labour's list of reserved occupations, and we learn that already some members of medical-library staffs have been called up for the Army, while others, less excusably, have been given notice to leave without any alternative work being offered to them

One final word Just as the healing art knows no national frontiers but is at the service of friend and foe alike, so medical science is international Though doctors are temporarily cut off from personal intercourse with their colleagues in enemy countries, they cannot afford to be deprived of the latest medical literature of such countries We are glad to hear that this question has already been considered by the Booksellers' Association and that a deputation is to be sent to the appropriate government department It is essential that no prohibitions on trading with the enemy should be allowed to hinder the exchange of medical information across national frontiers

SAFETY FIRST

IN spite of the instinctive contraction of expenditure in war-time, and the prospect of still heavier taxation, the practitioner is emphatically advised to maintain his membership of a professional defence society War may bring many medical men into even closer relationship with the public Previous experience indicates that, while hostilities are in progress, people are slow to embark upon litigation, but, when peace comes they bethink themselves of all sorts of legal rights, justified or otherwise It is common knowledge that nearly fifty per cent of the allegations of negligence and malpraxis occur when the doctor has sent in his account for fees The recovery of fees will not become more easy now, nor presumably will the allegations become less frequent It is not merely the worry of these allegations against which the practitioner needs to be protected When his defence succeeds, he may find himself unable to recover any costs from an impecunious plaintiff The report of the Medical Defence Union to be presented to the annual general meeting next week, contains evidence of the manifold risks to which the practitioner is exposed

ANNOTATIONS

PRESERVATION OF BLOOD FOR TRANSFUSION

MANY people nowadays are wondering how best to preserve blood for transfusion, and there is still no universal agreement as to the best anticoagulant. Until lately sodium citrate was almost the only anticoagulant available Heparin is now on the market but there is as yet no evidence that it has any advantage over citrate and expense seems likely to limit its use on a large scale. Sodium citrate was in general use before the question of storing blood for transfusion had arisen. On the assumption that a 3 8 per cent. solution is isotonic with human blood it was usually used in this strength Actually such a solution is isotonic with rabbit's red cells, whereas human red cells are isotonic with a 3 5 per cent solution The difference, however, is of little importance. The addition of 10 c cm of 3 8 per cent solution of sodium citrate to 90 c cm of blood has been used for a long time to prevent coagulation and is entirely satisfactory. Some workers use higher concentrations; Schöncher[1] recommends 5 c cm. of a 10 per cent solution to every 95 c cm of blood, giving a final citrate concentration of 0 5 per cent. Others, impressed with the possible depressant effect of an excess of sodium ions in the circulation, have used citrate in amounts to produce a final concentration as low as 0 25 per cent. (Knoll and Markl[2]); this has been equally satisfactory in preventing coagulation.

All simple citrate solutions are used in bulks of from 5 to 10 c cm to every 100 c cm of blood, thus producing minimal dilution of the blood. Under these conditions, blood keeps satisfactorily for a week or even longer. Thereafter some degree of hæmolysis appears and is invariably present after ten days Even in the face of slight hæmolysis, the blood may still be used for transfusion with satisfactory results Many attempts have, however, been made to devise anticoagulant fluids which would delay the onset of hæmolysis Most of these call for a much greater dilution of the blood than do the simple citrate solutions One of the first of these fluids was that of Bagdassarov,[3] usually known as I H T This is mixed with blood in equal volume and gives a final citrate concentration of 0 25 per cent , in addition to the citrate, it contains sodium and potassium chloride and magnesium sulphate Elliott et al[4] report favourably on it but Harrington and Mills[5] could find no value in the extra salts They recommend a solution of 1·05 per cent sodium citrate, 0 3 per cent glucose and 0 15 per cent. sulphanilamide dissolved in normal saline and added to the blood to be preserved in the proportion of 1 to 2; this gives a final dilution of the blood by one-third and a final citrate concentration of 0 35 per cent.

Only experience can show the ideal anticoagulant and preservative fluid for blood storage At present we may say that blood stored with sodium citrate added so as to produce the minimal dilution and to give a final concentration of 0 3 per cent citrate or over will form no fibrin; further, provided it has been kept sterile, it will not show hæmolysis for a week or even longer, and will remain suitable for transfusion for at least ten days. It still has to be shown that greater dilutions make longer storage possible It goes without saying that stored blood should be kept reasonably cool; a temperature of about 4° C is usually recommended and is quite satisfactory; refrigeration, although desirable, is not essential; granted sterile withdrawal, a satisfactorily prepared anticoagulant and clean bottles, blood will keep in a state suitable for transfusion in any cool room such as a cellar or larder for a week or longer.

SEEING IN THE DARK

THE blackout has made us more aware of the extent of the sensitivity of the retina when it is dark-adapted and the differences between vision during daylight and vision at night Hecht[1] defined the dark-adapted eye as one "whose sensitivity to light has reached a constant value as the result of a sustained stay in the dark" Before the eye becomes adapted there is a latent period of a few seconds when everything looks black, followed by a sharp rise in sensitivity for about 30 minutes, then a slowing, until at the end of an hour dark-adaptation is complete.[2] Vision in the dark-adapted eye takes place in the periphery of the retina and is a function of the rods in which the visual purple is contained. The central portion of the retina undergoes little or no adaptation and central vision is therefore not so good as peripheral This can be shown by looking at a group of stars directly—i.e., with central vision—when perhaps 4 or 5 will be counted. If, however, the group is looked at from one side so that the image falls a little distance from the fovea 6 or 7 will be visible Anything which interferes with the function of the periphery of the retina or the formation of the visual purple will prevent adaptation Night-blindness occurs in diseases of the pigment epithelial layer of the retina, such as retinitis pigmentosa Visual purple is said only to form when the rods are in contact with healthy pigment epithelium; night-blindness, however, does not occur in albinos.[3] During the last war night-blindness was found in conjunction with diet deficiencies and it responded well to cod-liver oil Vitamin-A deficiency has been found to account for night-blindness in some cases, and it has recently been suggested[4] that those about to undertake night work, such as driving a motor-car, should first fortify themselves with a vitamin-A concentrate in order to ensure the proper functioning of the visual purple

Peripheral vision is not nearly so acute as the central vision of the daytime, but in the dark-adapted eye movement is more clearly seen peripherally. Therefore, although it may be difficult to define the nature of an object at night if it moves, that movement can be seen—a fact of great importance when dealing with traffic in a blackout The clearness with which an object is seen depends very much upon its background Colour is recognised earlier if there is any illumination, however feeble, in its vicinity. Different colours are more easily seen on different backgrounds Thus red and yellow are seen earlier on white and green on black.[5] On a moonless night shadows are virtually absent, so that stereoscopic vision is less efficient, and distances consequently harder to judge. As the eye becomes dark-adapted the apparent brightness of colours changes In daylight yellow is the brightest

colour At night green becomes more easily recognised than yellow, blue, and red—in that order This fact becomes apparent on taking a country walk when the green of the grass becomes the most easily seen colour In the completely dark adapted eye vision is achromatic and all colours have the same hue, differing only in intensity

IMMEDIATE CLASSIFICATION OF HEAD INJURIES

THE early and wise classification of casualties is one of the most essential parts of war medical service Ambulances must not be filled with moribund or dead patients, when there are others whom surgery can save Sinclair-Loutit[1] emphasises the need for the special study of head injury in this light He points out that a patient who is in coma may merely be suffering from extradural haemorrhage which can be readily relieved by operation whereas a restless patient may have the mid brain sectioned and be beyond all help From his experience in Spain he concludes that the following three signs are of very grave import a continual discharge of cerebral matter, a very feeble pulse (the rate being less important), and what the Spaniards called "carfologia sexual"—a continual fumbling with the genital organs

Head wounds are never easy to classify, and the difficulties are greater under war conditions at a receiving-post It will probably be agreed that wherever there is a strong pulse the chances of recovery are fairly good even when the patient is deeply unconscious, provided any necessary surgical treatment can be promptly carried out On the other hand if a pure brain injury is associated with profound shock and coma, with a feeble and accelerating pulse, the prospects are poor At the same time it must be borne in mind that the signs of shock may be due not to the brain injury, but to some complication such as haemorrhage from the scalp, exposure or injuries to other parts of the body The neurologist can obtain further information in these cases from his investigation of the nervous system but the casualty officer may be advised to concentrate his attention on the state of the patient's circulation in his attempt to pick out cases suitable for major surgery He will do well to remember Sinclair Loutit's observation that many favourable cases are mentally confused or even comatose when the patient is first seen

A WAR-TIME PHARMACOPŒIA

THE upward movement in the prices of drugs has accelerated, it has also spread over a wide range of articles In some cases the advance in values has been great, but this does not necessarily imply that there is an acute shortage of such drugs, nor does it indicate that supplies cannot be replenished One of the reasons for the almost general advance in prices is the desire expressed suddenly and almost unanimously, on the part of all concerned to enlarge their stocks There is "a run on the bank" as it were and the bank has not sufficient bullion actually in its till to meet the run Nevertheless, the bank is solvent In the meantime importers of drugs and dealers and all others who constitute the central market for drugs have found it necessary to put a brake on the demands of customers who come to them with unusually large orders wisely enough manufacturers and wholesale dealers are rationing buyers, especially those who want to buy too much at once On another page will be found an indication of recent price changes In our correspondence columns last week the chief pharmacist of one of the large London hospitals suggested the need to husband the supplies of some of the substances of no great therapeutic value which are now being widely prescribed He had in mind such things as flavouring syrups, ointment bases and alcohol in tinctures, and he suggested the setting-up of a medico pharmaceutical committee to compile a formulary for war-time use It should, however, be borne in mind that we have a British Pharmacopœia Commission whose statutory duty it is to deal with precisely such circumstances as these, and although its ordinary work of routine investigation and laboratory control may lapse for the moment, an emergency organisation has been formed to deal with current matters as they arise While at present there are in this country ample supplies of drugs and other ingredients of medicines it may become necessary at any time to make changes in the B P formulæ or to introduce new formulæ in order to conserve supplies Changes of this kind can only be made official by means of an amending supplement or addendum published by the General Medical Council by virtue of its power under the Medical Acts These possibilities are, we understand, receiving careful attention, and communications for the B P Commission may be addressed to the secretary, Dr C H Hampshire, at 44, Hallam Street, London, W 1

ACCIDENTAL TRANSMISSION OF MALARIA

THERE are now many records of the transmission of malaria by blood transfusion, in some of which the donor has shown no sign of the disease for years and no doubt seemed a safe source of supply Lesne, Cayla and Lichtenberger[1] report the case of a child aged 7 months, suffering from severe bronchopneumonia who received seven daily intramuscular injections of the father's blood 60 c cm in all The child recovered and all went well for about two months when it developed the typical regular intermittent fever of quartan ague, and had twelve febrile paroxysms in all No malarial parasites could be found, but the child's spleen was enlarged and the condition seemed so obviously malarial that quinine was given and the fever ceased forthwith Six weeks afterwards there was a relapse which was again treated successfully with quinine, and two months later, although there had been no further febrile attacks, malarial parasites were found—young intracorpuscular forms, rosettes and a gametocyte of *Plasmodium malariæ* The source of infection was ostensibly the father, who was born in Cameroon and had lived there until thirteen years before, when he had come to France immediately after having had several attacks of fever, presumably malarial In France he had shown no signs of malaria, and an examination of his blood, made a week after parasites were found in his child, failed to reveal any parasites In *The Lancet* of Sept 2 (p 550) Dr Navarro and Dr I dward recorded a similar case in which an infant one week old received an intramuscular injection of 7 c cm of paternal blood for subarachnoid and gastrointestinal hæmorrhage which did not recur after the injection About five weeks later she developed restlessness anorexia and sweating, and had several small epistaxes and convulsions When the child was readmitted to hospital at the age of ten weeks her liver and spleen were found to be large there was high fever and blood examination revealed the presence of typical quartan parasites with severe anæmia She went rapidly downhill and died before

1 Sinclair-Loutit K W C, *St Bart's Hosp J* June 1939 1 136

1 *Ter Folyol. Med* 1939, July 15, p 92

specific therapy could be started. On post-mortem examination malarial parasites and brown granular pigment were detected in the liver and spleen. In this case, as in the former, the father was born in a malarious country—Ceylon—which he left twelve years ago,[2] and although he had been in the habit of taking quinine prophylactically he had never knowingly suffered from malaria and had been quite healthy since leaving Ceylon. Nevertheless, he was definitely harbouring parasites in small numbers, for, although blood-films at first failed to show them, the injection of 10 c.cm of his blood into a patient with general paralysis produced malaria in that patient, and the father subsequently had a short attack of fever during which a few parasites were detected in thick blood-films. Wright[3] has lately collected records of 29 such cases, in more than half of which the donors had never had recognisable symptoms of malaria. The possibility that donors from tropical and sub-tropical countries, however healthy, may be a source of malarial infection must be borne in mind when recipients develop fever of the tertian or quartan type, or, with a double tertian infection, even a sharp rise of temperature each day. Where infection is transmitted by blood-transfusion the incubation period will probably be short, and not unduly long as it sometimes is after intramuscular injection

A GREAT INVENTOR OF LITTLE THINGS

THE recent unveiling of a monument to the chemist Stanislas Limousin in his birthplace, Ardentes-en-Berry near Châteauroux, France, has revived the memory of a fertile inventor Limousin was born in 1831 and spent much of his comparatively short life (he died in 1887) in Paris where his pharmaceutical activities were prodigious All pharmacological problems in his day were at once put before him Consulted as to how obnoxious drugs could be swallowed, he promptly invented the cachet made of unleavened bread or wafer paper in which to wrap them. So simple! So ridiculously reminiscent of Columbus and the egg! When hypodermic medication came into fashion, Dr. Duhomme appealed to Limousin to devise some satisfactory means for providing sterile solutions of uniform strength He thereupon invented the glass ampoule which is employed to this day as universally as the name of Limousin is forgotten. This invention proved most welcome at the time, for toxic effects from overdoses and polluting infections threatened to bring discredit on the whole system of hypodermic medication. It was Limousin also who devised the 30-litre rubber balloons for holding oxygen, and his expert opinion was sought when the unlucky aerostat, the "Zenith," came into being. When the inhalation of oxygen was in fashion in 1874, Limousin organised an inhalatorium in his pharmacy where all who wished could breathe pure oxygen to their heart's content The list of drugs which Limousin unearthed from obscurity, and to which most of them seem sadly enough to have returned, includes piscidia and the sulphovinate of quinine, solutions of which he prepared for subcutaneous injection in malaria It was Limousin who, with his genius for solving big problems with simple devices, hit on a plan for warning the unwary about the poisonous properties of certain drugs Just give them an alarming colour! In due course official approval was given to this notion, and the sublimate of mercury issued to midwives was coloured with indigo-carmine. The automatic pipette was another of his inventions Strange that such a benefactor of the human race, so recently dead, should already have become as unknown to most of us as piscidia itself!

MORPHINE OR BARBITURATES BEFORE CYCLOPROPANE?

THE increasing use of cyclopropane gives importance to the selection of the most appropriate drug for premedication when one wants to give some adjuvant sedative or hypnotic before the anæsthetic itself The fact that cyclopropane is in no sense a respiratory stimulant—wherein it differs from some other anæsthetics—would in itself probably make anæsthetists chary of using beforehand any agent that tends to depress the breathing Chief among these is morphine, and the belief that this should be avoided before administering cyclopropane is strongly supported by some experimental studies in the United States[1] These show that dogs given morphine before cyclopropane react less favourably to the anæsthetic Not only is respiratory arrest more readily brought about but also certain irregularities appear before the respiratory arrest—a phenomenon rarely met in dogs having cyclopropane alone. On the other hand, the investigators found that barbiturates given beforehand had a beneficial effect, to the extent that dogs treated with them behaved better not only than those which had morphine but also better than those given cyclopropane only. They believe that whereas cyclopropane intensifies the bradycardia and arrhythmia of dogs given morphine, the barbiturates lessen vagal tone and decrease the irritability of the automatic tissues of the heart; a barbiturate should therefore be given in place of morphine when cyclopropane is used clinically These experiments will confirm a practice that has already been adopted, on empirical grounds, by a good many of the anæsthetists who have wide experience of cyclopropane

THE MINER'S IMPROVED LOT

AT the end of 1933 the number of men employed in coal-mines was 772,000, the total mining population being estimated at 3,000,000 Coal-mining is a hazardous industry and beside the risk to life there is hardship and discomfort, while, in the past, the amenities of the mining community have been too little regarded The recent annual report of the Miners' Welfare Committee[2] indicates a welcome change in attitude The receipts of the welfare fund amounted in 1938 to £819,458, and since the fund was started in 1920 a sum of £17,500,000 has been expended. A definite proportion of this money must by law be allocated to the provision of pithead baths, and grants for this purpose in 1938 constituted 62·4 per cent. of the total When present applications have been satisfied, 75 per cent of the workers will be able to bathe; those who still must do without are for the most part employed in quite small mines. The baths are equipped with first-aid rooms for the treatment of minor injuries, and with canteens. Illustrations in the report show the care which had been bestowed on choice of site and design The next item of expenditure, 17·2 per cent of the total in 1938 and 32 per cent. since 1920, has been in respect of recreation: the term covers 1400 schemes of varying type—parks, recreation grounds, children's playgrounds, institutes, libraries More direct health schemes include the provision and maintenance of

2. In the article by Dr David Nabarro and Dr D G. M. Edward, line 25 in col 2 of p 557 should read " . . the father was born in Ceylon in 1908 and had lived there until 1926 "

15 convalescent homes, and grants to hospitals, nursing and ambulance services. The last year has shown a new development following the introduction of holidays with pay, the Derbyshire committee has prepared a scheme for a chalet holiday centre at Skegness, with accommodation for 900 persons at a weekly charge of 8s. for adults and half that amount for children. The report indicates how much may be effected in industry by willing cooperation, vision, and humanity.

INOPERABLE CARCINOMA OF THE RECTUM

A PLEA to general practitioners to accept the serious responsibility involved in the management of cases of inoperable carcinoma was recently made by Dr. Thomas Hamilton of New South Wales.[1] It is wrong, as he says, to assume that an incurable growth precludes all chance of restoring the patient temporarily to active enjoyment of life. A great deal can be done by the personal interest of the doctor to allay the anxiety both of the patient and of his relatives. A diagnostic exploratory laparotomy has to be considered in most cases of abdominal growth. Hamilton thinks that it should be undertaken whenever the practitioner cannot be quite sure that operative cure is impossible. He also cites two cases, one of chronic pancreatitis and one of gastric ulcer, in which operation disproved the previous diagnosis of cancer. Occasionally, also, chronic constipation with faecal impaction may only be diagnosed at laparotomy. In advanced cases operation even if confined to laparotomy, may be enough to cause the patient's death, and this should be put before the relatives. Mr. Duncan Fitzwilliams, on another page of this issue, advocates laparotomy through a median incision below the umbilicus in advanced cases of rectal carcinoma rather than the performance of a blind colostomy. It is possible to give a much more accurate prognosis if the degree of extension and metastasis is known. Where radical removal is contra-indicated by local extension the patient's age or the general health, and where there are no metastases radium therapy and a well-acting colostomy have to be seriously considered. Fitzwilliams believes that the advantages of a colostomy are so great that it should be advised even before obstruction has arisen. The absence of irritation by the passage of faecal matter over the surface of the tumour lessens the inflammatory reaction and probably the rate of growth, and the general condition of the patient is improved and colicky pains disappear. Fitzwilliams thinks that in the advanced case there is no contra-indication to the use of radium and that nothing but good can come of its use. This is not a universal opinion for some surgeons are convinced that radium, while it may shrivel up the tumour does produce a very great increase in the pain. The chances of cure are much less than with such epithelial growths as carcinoma of the cervix and the screening of the radium must be efficient if untoward local reaction is to be avoided.

R. A. Gardiner[2] writing from the radium and X-ray department of the Prince Henry Hospital, Sydney, says that though radium has cured cancer of the bowel and in other cases has rendered inoperable growths fit for operation it cannot compete with operative removal. As might be expected the good results reported by him are in anal epithelomata. The two main methods he has used in carcinoma higher than the anal canal are the implantation of seeds into the growth and the application of tubes of radium or radon through a proctoscope or sigmoidoscope. Fitzwilliams has found the best method of application is by means of strands of twisted copper wire. He uses 20–30 mg. of well screened and protected radium mounted on four such strands and guides them through the structure by the finger or through the sigmoidoscope. The radium is left in position for twelve hours, and is then removed and inserted for twelve hours into the lower colostomy opening. If it has the effect of retarding the local spread of the growth and stopping the discharge of blood and mucus even for a time, there is a chance of improving the patient's general condition and mental outlook. The treatment of the anæmia which is so common is well worth undertaking, and intelligent care of the colostomy and instructions about suitable diet will make the patient less of an invalid. When to tell the patient the truth has to be decided in many cases. Hamilton thinks it is best to tell him the facts calmly and frankly at the stage when he has become impatient at his delayed recovery and at his increasing weakness. If he has had an exploratory operation he may have all along been uneasy in his mind that his recovery from the operation has not, as Hamilton puts it, been greeted with more enthusiasm by his relatives.

A TROPICAL RETROSPECT

Of all the themes for the medical historian, none is more fascinating than tropical medicine. The struggle against disease in the tropics has had for its setting India, Australia, and colonies and protectorates of the great powers, not to mention the Suez and Panama Canal zones. In two large volumes Dr. H. H. Scott[1] has traced the evolution of this branch of medicine with clarity, good judgment and humour. How far we have moved is shown by the description of conditions in the early days of the East India Company (for India, Scott acknowledges his debt to D. G. Crawford's "History of the Indian Medical Service"). At that time a surgeon-general on a salary of £20 to £30 a year, had not only to treat the sick but to cut every forty days and in a seemly manner the hair of the company's humblest employees. The story of yellow fever is intimately connected with the Panama Canal and Gorgas, "that modest little man with silver hair" as C. E. Flynn described him. He was ridiculed for his insistence on sanitation by the governor of the Canal Zone, and by the Canal Commission who elected to live safely in New York, and his displacement was determined on by the governor in favour of an old friend, an osteopath. A personal visit to the zone by the president, Theodore Roosevelt, made Gorgas secure by appointing him a member of the commission. Even then the chief engineer remarked "Do you know, Gorgas, that every mosquito you kill costs the United States Government ten dollars" to this the reply was 'But just think, Colonel, one of those ten dollar mosquitoes might bite you, and what a loss that would be to the country." Scott gives a delightful pen picture of Manson, working almost to the last "hobbling with the aid of a stick, or being wheeled from bed to bed in the hospital, benignant, kindly and sympathetic patient with everything but sickness and insincerity, courteous to all." One calls to mind the unrehearsed tribute to Ross when he was wheeled into a meeting of the Royal Society of Tropical Medicine and Hygiene to receive the Manson medal and the fellows stood as his chair passed forwards. Scott's book is a fitting tribute to these great pioneers of health in the tropics.

SIMULATED MENTAL DISORDERS AMONG SOLDIERS IN THE LATE WAR *

BY FREDERICK DILLON, M.D. Edin.

MEDICAL SUPERINTENDENT, NORTHUMBERLAND HOUSE MENTAL HOSPITAL, CHIEF ASSISTANT IN THE DEPARTMENT OF PSYCHOLOGICAL MEDICINE, UNIVERSITY COLLEGE HOSPITAL

THE diagnosis of malingering is often very difficult and any attempt to estimate the extent to which it took place among soldiers in the late war would be an almost impossible task. Conditions of life on the front were such that they provided the strongest motives for getting out of the fighting line, yet those with experience will, I believe, agree that few men attempted to do so by means of simulated illness It was interesting to see how naturally the process of adaptation took place to the fear- and horror-producing situations which constitute the psychological essence of war in the trenches This adaptation remained even in the last years of the war when the intensity of shell-fire became very great Sometimes the adaptation mechanism did give way, either as the result of too long continued strain or a sudden shock such as being blown-up or buried. Some were unfitted by temperament for the life from the start and were never able to adapt successfully. But it was an impressive fact that the ordinary man, coming from a peaceful occupation amid peaceful surroundings, rapidly and spontaneously accustomed himself to such an abnormal existence and settled down cheerfully to it

The constant strain of this strange life became clearer to the individual in perspective when, on account of sickness or wounds, he was sent away from his unit and his friends out of the fighting area He would have been more than human if he had not appreciated the relief, especially if the sickness or injury did not happen to be serious Among the war-neuroses seen at an advanced centre in France, malingering showed itself mainly as a tendency to perpetuate the existence of symptoms which would otherwise have passed away in due course, and to exaggerate the severity of those which were present (Dillon, 1939). Other cases, however, also appeared from time to time in which purely or largely artificial states were developed often of considerable complexity It is with these that this article is concerned The cases described include only those in whom evidence of malingering was considered to be conclusive

Simulated symptoms are generally considered to express a conscious and deliberate intention on the part of the individual, whereas those of the neuroses are looked upon as results of unconscious motivation The distinction between the two, however, is by no means sharply delineated. Conscious and unconscious motives may be combined and it is quite common for a malingerer, if he has undertaken to imitate an easily sustained disability, to become in the end persuaded of its reality—in much the same way as the man who recounts often enough an exaggerated story of his prowess comes in the end to believe it

CASE 1

A private in an infantry regiment, aged 28, was admitted to hospital in March, 1917, with a note from the regimental medical officer saying that he considered the man was unfit for duty in the trenches and should not have been sent back after a previous attack of shell-shock. When seen shortly after admission, the patient was in an intensely restless, excited state. He appeared to be constantly overcome by terror, acting as though he heard shells coming towards him Every sound seemed to send him into an extreme state of apprehension. He was apparently unaware of the nature of his environment, and took no notice of questions addressed to him He frequently went through an elaborate pantomime in which he would stare in terrified fashion in front of him, suddenly point ahead, utter some disconnected remarks such as "Germans!" or "over the top!" then cover his face with his hands and fall back on the bed, or suddenly dive under the bed-clothes. The condition appeared to be a confusional psychosis with vivid auditory and visual hallucinations He was given gr. 1/75 of hyoscine and quietened down at once.

The theatricality of the performance was impressive from the outset For three days the condition was kept up, and it was noted that the crises occurred particularly when he was under observation When he considered himself unobserved the confusion and terror seemed to disappear, but recurred at once if he was approached. Suspicions had by this time been aroused as to the genuineness of the condition. He was taken into the medical officer's room and, under careful questioning, information was obtained from him which could not possibly have been given if he had been in the condition of confusion his pantomime indicated. Confronted with the situation, he broke down and confessed that on being sent back to the trenches after treatment for a previous attack of shell-shock in another hospital, he could not stand the sound of the guns, but relapsed on the first day, began to shake all over and was again sent down sick. He had two-and-a-half years' service in the army and had been in France for six months He described how about six weeks previously, while with his battalion, he had been sent out on patrol with a party in no-man's land. The enemy's artillery opened fire and the party were forced to lie on the ground with the shells bursting round them for about twenty minutes The patient stated that he did not remember any more until he woke up in a shell-shock hospital, very nervous and jumpy. After about five weeks' treatment he was sent back to duty, but on the first day with his regiment broke down, as described above, and decided to simulate a condition which he hoped would bring about his transfer to England. The patient stated that he had been recommended for a decoration for bravery in the field, and had in his possession a white divisional card for good conduct. He expressed his regret and put forward a request to be sent back to his battalion in the effort to make good.

CASE 2

A private soldier, aged 20, was admitted into hospital in July, 1917, and remained for about three weeks in a state of apparent delirium. He sat up in bed most of the day staring fixedly in front of him, to all appearance oblivious of his surroundings and failing to understand what was said to him. He muttered continuously and unintelligibly, the only word which could be distinguished being "mother." There was no sign of disorder of any of the systems and physically he was robust He could do practically nothing for himself, had to be led about, required to be spoon-fed and obtained a good deal of attention from the ward sister. It was noticed that when approached by the medical officer the rate of his pulse went up, his breathing increased considerably, he perspired freely and swallowed frequently.

These signs, combined with the unusual nature of the condition, aroused certain misgivings. One day, as he was sitting in a chair and being fed by the ward

* Based on a thesis presented for the M.D. at Edinburgh University

orderly, I stood in front of him and carefully watched the proceedings. After some time his breathing became more rapid, his pulse-rate increased, he began to show signs of agitation and his face flushed. It was a reaction difficult if not impossible to reconcile with a genuine condition. He was taken into the medical officer's room, soon broke down under examination, and confessed that he had become increasingly nervous in the line and had assumed a fictitious condition as a means of getting out of it. He was overcome with shame at the failure of his deception. He covered his face with his hands and said "What will the Sister think of me!" This difficulty was smoothed over for him, but it created a sensation in the ward when he walked out of the room a normal man again, and aroused no little bewilderment in the orderly who had been feeding him but a short while before.

CASE 7

Among malingerers loss of memory was fairly common, especially in the later stages of the war. With Alan Breck Stewart in 'Kidnapped' these cases might claim to have "a grand memory for forgetting."

Sergeant C was admitted into hospital in May, 1918, complaining of headache and loss of memory. He stated that he woke up in a field the day before and found that his memory was gone: the last recollection he had was of being on the docks at Karachi in August, 1914, waiting to embark for France. A definite localised amnesia seemed to be present extending over a period of nearly four years. He remembered all his early life before August, 1914, and was able to give a detailed account of it. From notes sent down with the patient there was no evidence of any initial period of confusion such as occurs as a rule in cases of extensive amnesia. In conversation he was alert and bright, accurately orientated and normally quick in reaction time. His mental state was investigated by the free association method (Jung, 1917). In this a series of test words is given and the reactions noted. A number of significant words were included, designed to reveal the concealed complex which would be present if the patient were malingering. Such critical words as "trick" and "deceive" might be expected, in these circumstances, to produce a special reaction, for example, lengthening of the reaction-time and perhaps an unusual form of association. The results of the experiment are shown in the table.

FREE ASSOCIATION TEST ON SERGEANT C

Stimulus word	Reaction	Time in seconds	Stimulus word	Reaction	Time in seconds
green	grass	1·6	explode	ball	4·5
hammer	nails	1·5	continue	game	4
whistle	train	1·5	danger	train	4·5
nut	Spain	7	tree	branches	3
smoke	fire	2·5	go	away	5
fill	box	2	beef	steak	1·5
terrible	terrible to lose memory	1·2	sentence	5 years	3
			river	flowing	1·5
			bat	ball	1
trick	cards	10	dislike	hate	3
burst	bottle	3·5	watch	time	1·5
pay	pay	10	penalty	imprison-ment	2·75
for	ever	1·2			
force	driving	2	point	upwards	2·5
pint	handker-chief	1·5	burn	finger	1
			eat	dinner	1·5
will	dead man	5	key	door	1·5
deceive	wrong	13			

In the absence of proper apparatus, times were recorded with an ordinary watch. I estimated the probable upper limit of normal reaction time under the circumstances to be 3 seconds and regarded as significantly lengthened all longer than this. I had used the method previously in similar experiments on patients with genuine amnesia and had found it to be helpful. In Sergeant C the number of *complex-indicators* was so abnormally great and the reaction-times were increased in such a large proportion of the associations that powerful psychological forces, either conscious or unconscious, were obviously present. In a control experiment with the same list of words on a patient with a slight injury, only one complex-indicator was found—namely, the word "sentence." Even if we assume that this man had an exceptionally rapid reaction time and regard a wait of 3 seconds as abnormal only four complex-indicators occurred in the list of thirty-one words.

More increase in the number of complex-indicators is not however, proof of simulation. Most cases of the war neuroses show the same phenomenon. But on further investigation by the free association method, additional evidence was brought to light. For example, when the patient was asked to associate to them, none of the critical words were found to lead to any complex. To each of them a number of apparently indifferent and innocent associations was produced. Very striking also was the prolonged delay which occurred with practically every association that he made. There was no obvious reason why a person quick in mental reactions at other times should show this abnormal retardation under test conditions. The obvious inference was that he was concealing his thoughts, and was not responding with the first word that came into his mind as he pretended to be doing.

The evidence of the association-test was significant but not conclusive. In the light of later developments it appeared to have had an additional value, for it gave the patient the impression that his deception had been penetrated. Perhaps as a result, he almost at once started to exaggerate his alleged mental impairment and coloured the condition rather highly. To impress on the medical officer the simplicity of his mind about the newer inventions of the war, he volunteered the information that another patient had been talking to him about tanks. He had never heard of them before and wondered what sort of things they were. He had seen many of them go past the hospitals on trains, he realised that they were like the old "caterpillars," but could not see how a tank moved along. In view of his capacity to apprehend other things equally difficult, this apparent impairment of understanding was obviously assumed. Other weapons of war such as gas aeroplanes and the submarine, he "didn't seem to understand it." He had been reading, he said, in the newspaper of the sinking of a liner. He had never before heard of torpedoes, and he could not understand how anything from under the water could sink a ship that size.

Probably a conviction was forming in his mind that the evidence of his trick was increasing and that his embellishments had not produced the desired effect. At all events, a few days later he reported that practically all his memories had returned, in the following circumstances. The day previously, while at dinner he said, a wasp was flying about and he got up from his seat to kill it. Some one remarked that a wasp's sting was worse when it was dead than when alive, and another sergeant who was present observed that he once saw a man stung on the thigh. He had no sooner said this than the recollection came back to the patient of lying wounded on the thigh by a piece of shrapnel in May, 1917; it felt just like a sting at the time. He then got up, he said, went into another room and lay down on his bed, and his memories came back one by one. All the circumstances leading up to his present condition returned to him. He remembered being at his battery and starting out to reach a certain village. A salvo of shells came over, he jumped into a trench, something hit him on the left side of the head and he lost consciousness. He came to himself about two hours later lying on his stomach in a field feeling dazed, and covered with dust. He thought he was at the docks at Karachi and expected to see the troops about him waiting to embark. He got up and walked about half a mile then he came

over faint and sat down. When he woke up again—he thought about an hour afterwards—he could not remember anything; his mind was a complete blank. He started to walk along a road when a soldier met him and the patient inquired where he was. The soldier asked what had happened to him and he replied that he did not know. The soldier then took him to a dressing station at F——, and when he sat down he began to vomit. He was asked what his name was but did not know, so they went through his pockets and took out an envelope. When the patient saw the envelope he remembered his name and address, and, in fact, all his memories then came back except the period between waiting for the boat at Karachi and his "coming to" in the field. He could not remember anything of his life between those dates, and he had remained in that condition until the day before, when the episode of the wasp took place. Now, he said, all his memories had returned, except, curiously enough, the fact that he could not remember the identity of a girl who had written to him some weeks before. He could not remember receiving the letter, he said, nor the person who wrote it.

It was a circumstantial, realistic and plausible tale, and at the end of it he said he wished to express his thanks for the treatment. The story proved, however, to be almost completely fictitious. The following morning he confessed that the loss of memory had not been genuine. He had for some time been feeling increasingly nervous in the line and, in addition, relations had become greatly strained between him and the officer of his unit. On the day when he started for the village, shells came over and he got frightened and ran. He was not hit in the head, did not lose consciousness or lose his memory and the incident of the envelope which he had described was an invention. He met a soldier who took him to a dressing station, where he was so frightened that at first he could not give his name. He calmed down shortly afterwards, and as he found he was being sent to hospital he decided to keep up the deception.

CASE 4

Another case of apparent amnesia was that of a soldier who was sent into hospital in July, 1917, as the unidentified man. He had a gun-shot wound of the right hand, the middle finger of which had been amputated. He had been found, about six weeks before, wandering in a village not far from the trenches with the wound in his hand, and was taken to an advanced dressing station. There it was discovered that he had complete loss of memory for the whole of his past life. No information could be obtained from him regarding his name, regiment, home, or any of the details of his life. He did not know, for example, if he were a married man, if his parents were alive, or what was his former occupation. He had no identity-disc, pay-book or other means of identification on his person, and the following day he was sent to a casualty clearing station as an unidentified man. In the latter hospital after representatives from the surrounding regiments had failed to identify him, an attempt was made to obtain some information from him as he was going under and coming out of an anæsthetic, but without result. He remained there five or six weeks obtaining treatment for the wound and making himself useful in the ward.

When examined, he was found to be a bright, cheerful individual, clear in mind, able to understand perfectly what was said to him, and normally quick in reaction-time. He stated that he remembered everything since coming to at the advanced dressing station, but nothing of his life before that time. He could not read nor write, and was unable to name a letter of the alphabet written on paper before him. He declared that he could distinguish between what was writing and what was not writing. He had been in this condition since the time he found himself in the advanced dressing station about six weeks previously. There had apparently been no confusion at the dressing station and certainly not at the casualty clearing station the following day. There was no childishness of manner as was seen in many genuine cases of complete amnesia. His attitude was that of a normal grown man. He was sensible and rational in his conversation and he had no difficulty in apprehending what was said to him. There was no loss of the power to name objects, although, as already noted, he was unable to name the letters of the alphabet. He was capable of counting up to twenty-one, because he had helped the sister in the casualty clearing station who had twenty-one beds in her ward. Beyond twenty-one, however, he was unable to go. He showed no anxiety about his condition, accepted his severe disability with apparent indifference, and displayed no keenness or enthusiasm in filling-in the gaps of memory.

The condition was investigated along the lines described in the last case and within a few days his façade gave way and he confessed the imposture. He stated that he left his regiment when in billets and went up towards the trenches. He had had bad news about his wife and was feeling very worried and depressed. He intended, he said, to do away with himself and meant the shot which injured his hand for his head. When he fired and saw what he had done he "sort of came to himself" and realising the seriousness of his position threw away his pay-book and other means of identification. On being taken to the dressing station and asked his name he said that he did not know. As he found the deception was successful, he maintained it.

CASE 5

The varied symptomatology of the war neuroses made one speculate as to a possible relation between the strain of life in the trenches and the occurrence of a paranoid state with delusions of persecution. Theoretically it was not difficult to imagine a causal connexion and it was, therefore, a matter of considerable interest when the following case was sent into hospital in the beginning of September, 1918.

The patient, a private aged 22, was apparently very apprehensive. When brought into the medical officer's room he held up his finger, glanced over his shoulder and said "Hush!" He then leant forward and, in a whisper, said: "He keeps following me . . . Jerry; . . . all over the show . . with rosary beads round his neck . . . a big man . . . with black hair and beard and a yellow face." The patient would not speak above a whisper, because, he said, "he'll hear me." In fragments the history was obtained from him. He had gone "over the top" some days before with his battalion and taken the objective. He saw a great many dead Germans including the one who was following him about, who, he said, was strangled by rosary beads round his neck. The following morning they were relieved and went back to the reserve trenches. Two days later, when on their way up to the front line again, the patient said he felt that the German was following him. He turned round, saw the man behind him, and fell down in a state of terror. The German, he said, wanted to get his revenge as he (the patient) had killed a lot of his compatriots with bombs, "hundreds of times on raids." The history was extracted from him with some difficulty, and was accompanied by much screwing up of his face and pointing with his finger in the effort to remember. He frequently interrupted his story with such remarks as "I must go back," and "May I go back?" which seemed inconsistent with a genuine condition of extreme apprehension. On being examined, he would not close his eyes for the rhomberg test, as, he said, "he'll get me." The exaggerated and inconsistent features of the condition led to doubts of its authenticity and a pointed hint was given to him. The same evening he stated that he was much improved. The following morning he reported that the German had disappeared and thereafter left him in peace.

CASE 6

The detection of malingering was sometimes made easy by patients, who aspired too high in their flights of fancy It is probable, however, that other cases occurred which were never exposed, and from time to time dubious conditions were seen in which an assured diagnosis could not be made

A case in point was that of a man admitted to hospital in a condition generally resembling a psychosis His conduct was childish and silly He gave no real trouble, was clean in habits and enjoyed his food, but was untidy in his person and perverse in trivial matters Certain features suggested that auditory hallucinations were present and that dementia præcox was the probable diagnosis There were, however, other features with which this diagnosis could not be reconciled The following fragment of dialogue is the record of an actual conversation which took place with the patient, and is typical of the only kind of conversation that could be elicited from him

Medical Officer How are you getting on now ? Take the match out of your mouth How are you getting on ?—Patient Champion, sir

M O : Better than you were yesterday ?—P Champion, sir

M O Why do you keep your eyes closed ?—P What you were saying, sir

M O What did I say ?—P The same thing, sir

M O What do you mean by that ?—P Got it, sir

M O What have you got ?—P That

M O What's "that" ?—P Ingersoll watch

M O Why do you make gestures like that ?—P Because they are better ones than those ones

M O What are "those ones" ?—P These ones

M O What ?—P Those ones

M O What do you mean by that ?—(No answer)

M O What do those gestures mean ?—P Life, sir

M O What's that ?—P Polar bear, sir

M O Why are you stretching out your hands ?—P My power, sir

M O What power ?—P What you said, sir

M O Why do you make those faces ?—P Très bon, sir They are champion sir Très bon Looks champion sir

M O : What looks champion ?—P Ah ! Très bon, New ones

M O New what ?—P Boots sir What time is it now, sir ?

M O What time do you think it is ?—P I think it's about one o'clock, sir Do you mean that, yes ? Take it then

Even after the case had been under observation for several weeks, no definite decision as to the nature of the condition could be arrived at and he was evacuated to the Base

The main difficulty at our advanced centre was the lack of psychiatrically trained medical staff A further drawback was that in the different phases of the war the numbers of patients varied considerably, during a push we were often swamped with new cases At these rush times, it is probable that a number of malingerers escaped our vigilance and were evacuated to the Base along with the severe cases It is essential that medical officers at advanced centres should bear the question of malingering constantly in mind At the same time, even in spite of psychiatric experience the diagnosis may be extremely difficult, as has been shown above If injustices are to be avoided, and unnecessary compensation and pensions saved it is essential not only that diagnostic psychiatrists should be available, but also that facilities for observation as long as may be necessary should be at hand

PROFESSIONAL EXAMINATIONS

THIS AUTUMN

ENGLISH CONJOINT BOARD

In consequence of the outbreak of war the committee of management of the Examining Board in England has authorised the following arrangements and modifications in the regulations for the L R C P, M R C S Section 1 of the final (pathology and bacteriology) will be discontinued Candidates who have already passed section 2 (medicine, surgery and midwifery) should inform the secretary of the board of the date on which they passed in the last subject Arrangements will then be made for their names to be submitted to the Royal Colleges, so that they may be granted the diplomas of L R C P, M R C S Candidates for the final qualifying examination will be allowed to complete the examination on producing evidence of having done thirty months' clinical work after passing in anatomy and physiology, provided that all the specified appointments have been held Candidates who have done twenty-four months' clinical work after passing in anatomy and physiology will be eligible for admission to one or two subjects of the examination The regulation requiring the whole of the final examination to be completed within a period of twenty five months is suspended

It is anticipated that the first examination (anatomy, physiology, materia medica and pharmacology) will begin on or about Wednesday, Oct 18 Candidates will be eligible for admission to part I (anatomy and physiology) on producing evidence of forty-six weeks' study in anatomy—including dissection of the entire cadaver—and physiology, all of which may be completed within a period of twelve consecutive months Owing to the postponement of the examination, entries will be accepted up to the first post on Wednesday, Sept 27

It is expected that the premedical examination (chemistry, physics and biology) will begin on or about Monday, Oct 23 Further particulars of the first and premedical examinations will be sent to candidates as soon as they are available

The examinations for the Diplomas in Child Health and Public Health due to begin in September and October respectively are postponed for the present Further information will be published as soon as it is available

Candidates for all examinations must be prepared to be examined outside London if necessary

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The final examination for the Fellowship will, it is expected, begin on Nov 9 and the primary examination on Dec 4 as advertised

The final examination for the L D S will it is expected, begin on Oct 27 as advertised The first examination for the licence, advertised to begin on Sept 20, is postponed for the present

Candidates who enter for the examinations by the appointed dates will be sent further particulars when arrangements have been completed

SOCIETY OF APOTHECARIES OF LONDON

The examinations conducted by the society will as far as possible, be continued under existing regulations, but the following modifications are announced

The premedical examination in science will be discontinued for the present Examinations of other boards which admit successful candidates to registration as medical students will be accepted as usual

For the primary examination evidence of a period of forty-six weeks study in anatomy and physiology, which may run concurrently, will be accepted in lieu of the five terms laid down in the regulations

Students will be allowed to complete the final examination on showing evidence that they have held all specified appointments and completed a minimum of thirty months clinical work after passing anatomy

and physiology, and will be admitted to one or two subjects of the examination on the completion of twenty-four months of such study. The regulations which demand the completion of the final examination within a period of twenty-five months will be held in abeyance The hours at which examinations are held will be regulated as far as possible to ensure completion during daylight. candidates should note carefully the times of attendance indicated on their cards of admission.

PUBLIC HEALTH

Health-Instruction Officers

BEFORE the outbreak of war the Nottingham county council were considering the appointment of a health officer to coördinate instruction of the community Such officers are not uncommon in the United States, but so far we have had none in this country, though we have many unofficial health instructors, from newspaper correspondents to public lecturers, and health teaching is one of the cardinal duties of every health officer

The chief work of a health-instruction officer is to retail physiological sciences to the community in a form which the public can digest, but in addition he should be able to translate research into terms of action for the benefit of health officers The Medical Research Council, the Industrial Health Research Board and all other bodies and persons engaged in furthering the science of medicine complain bitterly and frequently that the goods they deliver are not utilised and that discoveries with wide possibilities of practical expression lie on the table for months or years—often until they are forgotten. Nobody can be blamed for this, for the language of research is not that of medical practice, the language of medicine is not that of the people, and there is no interpreter.

Notts county were prepared to consider appointing a health-instruction officer if a suitable candidate could be obtained, but doubt was expressed whether any was forthcoming. In our issue of July 22 we published an address by Dr Iago Galdston of the New York Academy of Medicine, entitled The Health Educator, which gives a clear view of what such a person should be and how he should act From this it is obvious that efficient public health instructors will not be obtainable easily, for those possessing all the necessary attributes can command high places in numerous branches of industry, but in a peaceful world in which the object of governance is the prosperity and happiness of the peoples, the position of health instructor would be highly attractive to persons of superior wisdom

Medicine for Evacuated Children

Correspondence has passed between the Ministry of Health and the organisations representing pharmacists concerning the supply of medicines for unaccompanied children who have been evacuated under the permanent scheme It would seem that in making provisional arrangements with the Central Emergency Committee for medical attendance on such children, including the supply of medicines, the Pharmaceutical Emergency Committee was not consulted The Minister of Health has now explained that it is not proposed that payments to doctors should be made at a capitation rate; in fact it seems doubtful whether such a basis could be adopted in view of the uncertainty of the duration of the stay of each child The Ministry's proposal is that the amount to be allocated by the Government for each reception area, although calculated in the first instance at a flat rate of 10 shillings a head, should be handed over to the local medical emergency committee, who will evolve their own scheme for remunerating the doctors either on the basis of payment per visit or such other basis as they may consider appropriate The Ministry, in a communication to the secretary of the National Pharmaceutical Union, says "the doctors will doubtless follow their normal practice in the matter of supplying medicines or giving prescriptions, and in either case the cost will be met out of the local pool" The Ministry understands that in some areas doctors who are not accustomed to dispensing have expressed a wish to be allowed to give prescriptions which could be dispensed by any chemist. Although the children are not insured persons the Ministry is prepared to agree that the pricing bureau under the National Health Insurance scheme may be used for the purpose of allocating payments to the chemists in respect of medicines so supplied. It would be well if the local medical and pharmaceutical committees were able to agree on terms which will make for the smooth working of this emergency scheme.

The Weekly Return

In his weekly return (*1939, no 36*) the Registrar-General points out that the return of deaths relates to civilians only—i.e., it excludes the deaths of serving sailors, soldiers and airmen The births and deaths assigned to towns or other areal divisions of England and Wales are those actually occurring in the respective areas without regard to or adjustment for usual residence Furthermore, owing to the partial evacuation of populations from London and some of the large towns, the weekly birth- and death-rates cannot be calculated with accuracy and are discontinued for the present The estimated populations at the middle of 1938 (given in table 1) no longer correspond even approximately with the deaths in that table for many towns, but being the latest available estimates of the populations normally resident therein they are still included

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 9, 1939

Notifications.—The following cases of infectious disease were notified during the week Smallpox, 0; scarlet fever, 1106; diphtheria, 782; enteric fever, 77; pneumonia (primary or influenzal), 237, puerperal pyrexia, 166; cerebrospinal fever, 10; poliomyelitis, 30; polio-encephalitis, 1; encephalitis lethargica, 1; dysentery, 19; ophthalmia neonatorum, 78 No case of cholera, plague or typhus fever was notified during the week

Deaths.—In 126 great towns, including London, there was no death from smallpox or scarlet fever, 2 (0) from enteric fever, 2 (0) from measles, 8 (2) from whooping-cough, 19 (0) from diphtheria, 43 (1) from diarrhœa and enteritis under two years, and 5 (1) from influenza. The figures in parentheses are those for London itself.

Ilford and Gillingham each reported a death from typhoid Wolverhampton had 2 deaths from measles, Birmingham 3 deaths from whooping-cough Fatal cases of diphtheria were scattered over 13 great towns, Sheffield reporting 3, St Helens, Walsall and Plymouth each 2. Liverpool had 7 deaths from diarrhœa, Hull and Wolverhampton each 3

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month, his name can be seen later in the half-yearly index

FROM D P M

IV

How are we going to fill in our spare time while Mr Chamberlain and his colleagues are polishing off the Nazi regime? That is what institution dwellers are asking themselves at the moment Herodotus records that during a shortage of corn the Lydians invented games, they had games all one day and *no dinner, and the next day they had dinner but no* games He *mentions* dice ball, *and* bucklebones among their inventions and adds that in fact they thought of all the games except draughts—which looks as though we have to thank the Lydians for snakes-and-ladders and ludo However after eighteen years even the Lydians got tired of this arrangement, so they drew lots and half of them moved out, leaving presumably, a daily dinner for all So much for the Lydians, as Herodotus would say, and as we may fairly hope for dinner as well as games we ought to be able to last out twice as long as they did

The problem is not really frivolous Nurses come off duty at seven in the evening, by eight it is dark, and soon they will have no daylight off duty time at all London, after dark though perhaps not a wicked city at present, is certainly a dangerous one, as those who drive by night know Many nurses wisely stay in the hospital, though now that the cinemas are open again they will have more occasion to risk their limbs Still they cannot spend all their free time in cinemas, and there is little enough to occupy it in hospital It would be a good opportunity for study had not even the mild excitement of the R M P A examination been taken from them Nurses who have no practical use for the information sit like a row of unresponsive muffins before the sweating lecturer I can't seem to take any interest in this stuff now," one willing girl said sadly

This interruption of education is, I suppose inevitable, or is it? Have we perhaps overshot the mark again and been too careful? In the last war we certainly rushed a large number of nurses and doctors through their examinations in order to avoid a shortage, and perhaps this meant that the standard in the two professions fell a little—at least as far as theory went, practical experience was probably wide enough to outweigh this defect The standard is just as likely to fall and to fall heavily it seems to me under the present system If medical students and probationer nurses are to be kept in a state of suspended education for any length of time their enthusiasm is likely to evaporate The Conjoint Board, with engaging phlegm is carrying on with its examinations, perhaps we can hope that most of the other examining bodies will presently pluck up spirit to do likewise

* * *

Common usage is said to be the final criterion in settling the meaning of a word, but the fate of the word 'evacuate' at the hands of the common user, and even of the B B C calls for a mild protest at the present time I can see that it is possible to evacuate London but is it really possible to evacuate a child—except by catharsis?

Anyhow, in one village they were waiting for their quota of these evacuated children, buns chocolate and bumpers of milk, designed I suppose to fill the vacuum, were laid out in the local school room, and the matrons of the village had collected to welcome the little ones Night fell and the matrons went home Next day they came again, and the day after, but no children appeared The milk had to be replaced, the buns got stale, and the less conscientious matrons began to nibble at the chocolate, now a little dusty In the early days of the vigil speculation on the appearance of the children ran high, for each matron had applied for a blonde, blue eyed female child aged five, and had expressed her determination not to be put off with a healthy boy of eleven or so with muddy boots However, as the days went by decision faltered, and it was generally felt that the sight of any sort of child would make a welcome change Finally word came that each of the neighbouring villages had double its quota of children, but that their own village had been overlooked, and owing to some regulation or other it was impossible to switch the excess children over into the empty village

This story rather cheered me, as it looks as though we may be muddling along in the same old way after all

* * *

I have just been hearing *some facts* new to me, about ancient weapons of war They seem encouraging Most of us are inclined, I think, to compare modern warfare gloomily with the home made efforts of our forbears in the belief that we can now kill more people more cheaply, quickly and disagreeably than they could However, as so often happens with scientific advances we turn out not to have been very clever after all The six foot longbow, I am told used by an expert loosed a clothyard arrow with a force of anything up to a hundred and fifty pounds, capable of piercing steel armour like cheese, more over being barbed and spinning it made a wound more commonly mortal than not The knight hit by an arrow observed the rules of battle and gave no more trouble to the enemy that day, and even a charging lion is said to be stopped more certainly by an arrow than a rifle bullet Bullets indeed move faster than arrows but are not mortal unless they hit you in one of the right places

Then again, the method of joining battle in the past made for a high mortality rate, you picked out some fellow on the opposite side and went on fighting him until one of you lay down Thus ensured a fifty per cent mortality in every single combat, with a chance of raising the figure to a hundred per cent by the time the army surgeon had done with the victor These would be regarded as impossibly high figures in modern war I recall one of *The Lancet* staff telling me that whenever he read about the pessimists going out armed 'only with hills' his sympathy was strongly with the enemy Clearly they would be less dangerous if armed only with machine guns which require an expert to use them

And finally civilians may recall for their comfort that when our forefathers took a town they sacked it, and sacking was sacking in those days, there was no talk about sparing the women and children or respecting the Red Cross or anything of that kind They made the party as unpleasant as possible, and

it was the more unpleasant to my mind because it was held at close quarters Death was not sprayed impersonally from the air; you saw your fellow man drunk and distorted and mad, carrying out deeds which would be dreadful to him ever after How much more agreeable to receive a bomb through the roof of your own home as you sit among your family doing the evening cross-word And in any case the chances of being hit are far smaller than the chances of not being hit, while the chances of escaping attention during the sack of a city must have been poor. In fact if we can put up with the bangs we shall have very little to complain of, thanks to the march of science.

* * *

A Spanish girl who has been watching the air-raid precautions in one of the outlying shires cannot get over her amusement at our concern for ourselves The Spaniards carried their war, it seems, with a lighter touch, they popped into the local cinema on their way out of a crumbling town, and when they used gumstrip they used it coloured, and stuck it on their windows in fancy patterns So far I have seen no advance on the Union Jack in window decoration over here, it makes one feel rather shamefaced "Surely," someone said to me the other day, "this is not the way that England used to go to war?"

No, this is a new way, certainly; and of course in some respects a better one There is no cant, no cheering and no chat about glory this time, for which we must all be thankful, but on the other hand there is this dreadful solemnity, as though we thought we mattered It makes one wonder how we became so inflexible, and whether invasion by a lot of total strangers would be quite the disaster we all imagine Though heaven forbid it should be a German invasion: the Germans are too much like ourselves in being willing to submit meekly to a mass of regulations What we want is a change, and I can't help thinking it would do us no harm to be invaded by the French, they have such a good sense of values and are not preoccupied by the trivial in government It is nearly a thousand years since the last French invasion of this country, and the old Anglo-Saxon has got the upper hand again How the Normans must have enjoyed upsetting the old English customs, shocking the local dignitaries and bringing their vulgar candid wit to bear on Anglo-Saxon politics The trouble is, however, that if people live long enough in England they become English, I think it must be something to do with the climate,- they become—roughly speaking, of course—rather grave and sentimental, with a simple faith in British institutions At the moment our simple faith seems to have got the better of our Norman blood, and it has not needed a war to bring this unfortunate fact to light We have been growing too well-regulated for a long time now, multiplying restrictions on eating, drinking, smoking, parking and crossing the road until we expect to be told how to carry out the most elementary processes. I remember once being asked—not by *The Lancet*—to write an article on "How to Breathe"

Our chances of a French invasion are of course rather slight at present, but the strain we inherit from that race of brilliant realists should help us to shake off our present mood of fussiness, or what is to become of the famous "sangfroid habituel" which the schoolboy had trouble in translating?

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

REGIONAL OBSTETRICAL SCHEME

THE Department of Health for Scotland has organised a regional obstetrical service for areas distant from the large hospital centres Obstetrical consultants have been appointed to organise and run hospitals in Dumfries, Inverness and Perthshire. The service is designed as a war-time measure for the care of pregnant women who have been evacuated from the danger areas of Edinburgh, Glasgow, Clydebank, Rosyth and Dundee, in addition to those already living in the reception areas In peace-time pregnant women have when necessary been sent to the large hospital centres, or consultants have travelled from these centres to the smaller towns In war-time, however, transport of either patients or doctors is difficult or impossible, and further the local practitioners are already overworked owing to the depletion of their numbers Hence the need for the new scheme The Dumfries service is designed to cover not only the town but also the counties of Dumfries, Kirkcudbright and Wigtown; because of the difficulty of reaching the patients' homes as many as possible will be brought in to the regional centre for delivery. Antenatal clinics will probably be set up in several smaller centres Dr J Bruce Dewar has been appointed for whole-time work in Dumfries, Dr Caroline Elliot for Perthshire, and Dr. T. N. MacGregor for Inverness.

MEDICAL EXAMINATION OF EVACUATED CHILDREN

Many complaints have been received from reception areas about evacuated children having been sent without adequate medical examination. The inevitable cases of infectious diseases have cropped up, but the chief complaints have been of scabies, pediculosis, ringworm and impetigo Householders have stated that bedding and furnishings have had to be burnt Taking the evacuation as a whole, these are minor if unpleasant worries and they must be put down largely to the suddenness of the exodus and the time that Hitler chose—just at the end of a long holiday before the school medical authorities had an opportunity to examine the children Further evacuation is only likely to be carried out in small groups, and assurances have been given that the children will be examined and their equipment attended to before they leave their home towns.

CERTIFICATION OF DEATHS

SPECIAL arrangements have now come into force for the certification of deaths due to war operations. Bodies not claimed by relatives will be taken to a mortuary, and the clerk to the council will send the registrar a certificate that death was due to war operations. In the case of serving sailors, soldiers or airmen, and of certain classes of civilians employed with the armed forces, commanding officers are authorised to issue a certificate. The ordinary procedure will apply to other deaths. A medical practitioner who was in attendance on a deceased person prior to death should issue an ordinary death certificate and should add the words "war operations" to the particulars of violence. When no doctor has been in attendance before death the relatives may request one to inspect the body and issue a certificate and if he is satisfied that death was due to war operations, he may do so. He should complete the ordinary certificate, deleting the words "last seen alive by me" and "not seen," thus indicating that the deceased was seen after death but not before Whether the doctor has been in attendance or not there will be no need to report these deaths to the coroner and no inquests will be held on them.

LETTERS TO THE EDITOR

THE WAR AND THE R M B F

SIR,—In spite of the unprecedented difficulties which members of the medical profession are experiencing owing to the war, may I appeal through you, Sir, to all our regular subscribers, who have not yet sent in their contributions to the fund for the current year, to do so now or as soon as possible If we are to do our part, as the profession will expect us to do, in continuing to help our aged beneficiaries, and also those who may suffer privation owing to the war, it is vital that we should receive financial support not only from our regular subscribers but from every member of the profession

Cheques should be made payable to the Royal Medical Benevolent Fund and sent to Wormingford Grove, Wormingford, Essex

I am, Sir, yours faithfully,

LEWIS G GLOVER
hon treasurer

Sept 18

MEDICAL CARE OF CHILDREN IN THE RECEPTION AREAS

SIR,—Since we have evacuated children from our larger cities to save them, if possible, from the risk of bombs, we needs must act quickly to minimise the possible toll of disease To organise the medical services of the nation in face of this vast dislocation of the life of the people was a superhuman task So far the bombs have not descended on us May we take advantage of this breathing space to deal with some of the more obvious gaps in our medical arrangements? Of these, one is certainly medical provision for children in the reception areas, another (with which I am not concerned in this letter) is provision for children in London, where thousands of children remain Let alone the risk of epidemics in rural areas resulting from the mass migration of children, we need to bear in mind that the children are of necessity often billeted in the houses of persons with scant knowledge of children, healthy or sick, and also that scattered in country districts are many hundreds, nay thousands, of infants and children who, but for the war, would be inpatients in city hospitals or under skilled supervision in outpatient clinics Moreover, mothers of artificially fed babies in country districts are likely often to be unable to get the particular dried milk or infant food with which they are familiar—a small point one would say, but infants may quickly come to grievous harm from want of some elementary instruction in feeding

It is said that some mothers are bringing sick children back to London because they hope thus to get the medical help to which they are accustomed, and children with minor infections have in some instances been sent back to London by local authorities for treatment There is at present not only a shortage of medical help in rural areas, but the health visitors and school nurses of London who would normally be concerned with the welfare of the children have been drafted to other work in first aid posts and hospitals

Presumably the authorities will aim at providing in the reception areas

(1) Clinics for infants and children of all ages at which advice will be given and minor conditions treated

(2) Clinics with facilities for laboratory and other investigations

(3) Inpatient accommodation with full hospital facilities

(4) Beds for sick children unlikely to require more than simple nursing and medical supervision

(5) Beds for infectious diseases

(6) Treatment by general practitioners

Of arrangements to provide (1) to (5) I know nothing, except that in one sector a paediatrician has been appointed to take charge of thirty odd beds for children (when these are available) and presumably to start clinics, (6) must of necessity take some time to organise Meanwhile so far as I gather most London paediatricians are unemployed, whether they are sitting at home or are called up to act as general physicians at empty base hospitals Cannot they be utilised at once in their own sphere, to set up what we may call paediatric units in the various sectors or other reception areas and to form the skeleton of the required services other than the general practitioner service?

To begin with they might institute clinics, some in village halls, some at hospitals, some perhaps in empty houses which might eventually form small hospital units on the model of school sanatoria Their services would be available when epidemics appeared in schools On such beginnings a more adequate medical provision could be built up Each paediatric unit might consist of the paediatricians allotted to the sector or county, a central dispensary and store, and a central laboratory or a share in such a laboratory A travelling dispensary van and dispenser would be an asset As the scheme developed the help of an orthopaedic surgeon, psychiatrist or other specialists might be enlisted, or existing orthopaedic clinics would no doubt assist Naturally the whole of the work would have to be coördinated with that of the medical officer of health and the local medical emergency committee Beds for sick children (both in fully equipped hospitals and probably in small groups in villages) are likely to be required on a fairly large scale, as temporary hosts will often be unable or unwilling to accept the responsibility of a sick child, and the paediatric unit should be available to give help when needed for any such beds

Our health services for children in peace time have suffered from the divorce between hospitals (voluntary and municipal), school medical service, child-welfare service and general practitioner service May this prove an opportunity for linking up some of our work for child health in the reception areas

I am, Sir, yours faithfully,

HELEN M M MACKAY

London, Sept 18

MONOCYTIC ANGINA?

SIR,—I have read with interest the account of a case of monocytic angina treated with M & B 693, recorded by Drs Hugh Stannus and Marshall Findlay in your issue of Sept 9 The prime interest of their case lies, of course, in the transmission of the infection to the rhesus monkey as a further step in the ætiological investigation of the disease But they also stress the dramatic—this overworked word must still be used for many results of sulphonamide therapy—cure brought about by M & B 693, though they point out that the action of the drug may only be on the secondary throat invaders For a striking feature of some cases of monocytic angina is the late period of onset of a severe throat lesion which does suggest a secondary invasion of weakened tissues I have recently had under my care a typical example of this disease, similar in most respects to that described by Stannus and Findlay A large mass of glands in the right side of the neck, developing a week before the severe tonsillar infection gave an early clue to the diagnosis and suggested the advisability of a blood-examination the latter revealed a marked increase

in the mononuclear cells Eventually the throat condition became much worse, with temperatures up to 104° F., and the patient appeared very ill indeed. Treatment with M & B. 693 orally in full doses was instituted at this stage, and the clinical picture completely changed in 24 hours

Monocytic angina is a strange clinical syndrome, presenting varying pictures The prodromal symptoms are vague malaise, headache which is often severe, slight pyrexia, occasionally epistaxis, and usually a slight soreness of the throat The diagnosis can hardly be suspected until the adenopathy appears, and it is obvious that a correct diagnosis must often fail to be made; many cases, I imagine, are labelled Vincent's angina, since the textbooks state that severe throat involvement is rare in monocytic angina. But the appearance of the cervical adenopathy *before* the throat signs or symptoms are at all conspicuous should suggest immediate examination of the blood

I fear that before very long the precise diagnosis will have only an academic interest, for who can resist giving a sulphonamide derivative to the non-diphtheritic "throat"? No thoughtful clinician likes to see his obscure pyrexia cured by hit-or-miss therapy before he has arrived at a diagnosis, provided his patient is not deteriorating, but this academic catastrophe must be happening every day with a drug so wide in its therapeutic actions as M & B. 693. However, we are gradually learning what infective processes are not aborted by the drug, and thus its exhibition is coming to have a value in diagnosis, as well as in treatment

I am, Sir, yours faithfully,

Liverpool, Sept 11. RONALD ELLIS.

REGIONAL ORGANISATION

SIR,—War will probably make a national medical service a necessity Those who have desired and worked for this in peace-time may now have an important duty. Opposition has been based on two fears, firstly of bureaucracy, secondly of financial loss by some individuals The second will no longer count for much if, as one hopes, some method is found of ensuring that inevitable reductions in standards of living are fairly distributed (it would be shameful if the heaviest losses were suffered by the families of those whose lives were at greatest risk on active service and war were made a source of profit to others) Paradoxically, peace-time advocates of a comprehensive service who saw the risks of administrative bureaucracy and tried to avoid them in their plans are likely to see their former opponents accept any sort of regimentation without demur now that their patriotism is obviously involved. Conscription of doctors is a necessity, but authoritarian organisation is not Regional organisation based on hospital and public-health centres will almost certainly develop; such centres should have the greatest possible degree of local autonomy on a representative basis, and acting medical staffs of all grades should have both a consultative function in policy and the greatest possible freedom of individual professional action The war committees of the British Medical Association, which are representative of the profession, should be able to play a critical part in ensuring that the principle of freedom of professional conduct is upheld as strongly as necessity allows, and that place-seeking nepotism and arbitrary exercise of authority are reduced to a minimum.

I am, Sir, yours faithfully,

B LEYS,
Consulting Physician Royal Northern Infirmary and Highlands and Islands Medical Service

Sept. 13

PREVENTING VACCINATION SEQUELÆ

SIR,—At the present time large numbers of persons will necessarily be vaccinated I would stress the importance of disinfecting the pustular mass on the sixth day after vaccination with potassium-permanganate compresses. The results of such compresses are first and least important a black scab, secondly a material reduction in discomfort, and thirdly a considerable lessening of septic sequelæ By experiment it has been shown that if a subject be vaccinated daily, on the fourth or fifth day the vaccination ceases to take, also if the vaccination area be excised on the fifth day subsequent vaccination does not take Vaccinal immunity is therefore established on the fourth or fifth day, and nothing is lost by disinfection of the vaccinal area on the sixth day The advantage of so doing is substantial The technique is really an extension from the well-known treatment of smallpox with potassium-permanganate baths

I am, Sir, yours faithfully,

West Wickham, Kent, Sept 9 R W JAMESON.

A WAR-TIME PHARMACOPŒIA?

SIR,—Mr. Davis suggests that a war emergency pharmacopœia should *now* be devised It may be useful for it to be known that machinery was set up some time ago and plans are already well advanced for the production of a revision of the British Pharmacopœia This will include substitutes for many foreign proprietaries in common use which can equally well be produced in this country once the patent and trade-mark rights on them have lapsed It can be confidently anticipated that the Board of Trade will cancel certain foreign patent and trade-mark rights, as was done in the last war, and there is no doubt that the machinery of the General Medical Council, which is already in being, will be able to introduce these substitutes with very little delay should it become necessary to do so The G.M.C. will also give, as they did in the last war, attention to the conservation of supplies of essential items of materia medica and the eradication of non-essentials The Ministry of Health have also been giving attention to the conservation of supplies of essential drugs

Regarding formularies, it will be appreciated that the existing pharmacopœias of some of our larger hospitals are specifically designed to combine the greatest economy compatible with the maximum therapeutic efficiency. The National Formulary also follows these lines to some extent, although further economies could probably be effected. In the meantime, however, medical practitioners could give invaluable assistance by adhering strictly to published formulæ and by refraining from prescribing proprietary articles, particularly those of foreign origin.

I am, Sir, yours faithfully,

JAMES COUTTS,
Sept. 16 Pharmacist to St Bartholomew's Hospital.

MALARIA THERAPY CENTRE AT HORTON

SIR,—Of recent years many cases of neurosyphilis have been treated by malaria therapy in the London general hospitals Those facilities for treatment no longer exist I am writing to say that the Ministry of Health, in conjunction with the London County Council, have made arrangements for the malaria therapy centre at Horton Hospital, Epsom, to continue Accommodation can be provided for private patients (at an inclusive cost of 4 guineas a week), voluntary and certified patients All rate-aided patients should have a London settlement Inquiries regarding possible admission should be addressed

in the first instance to the M O in charge of Malaria Therapy Centre Horton Hospital Epsom from whom the necessary application forms for admission can be obtained (Telephone number Epsom 9872)

I am, sir yours faithfully

W W NICOL
Medical Superintendent Horton Hospital

Epsom Surrey Sept 18

THE BLACK-OUT HABIT AND STALENESS

SIR,—We must all do our best to make the black-out effective for its purpose The Prime Minister says that the restrictions are required on strategic grounds and are the result of long experiments by the R A F They are for the moment inevitable', "preparations for blacking out at the last minute would be too late", 'lighting in remote areas would be a signpost to built up areas" Changes cannot easily be made 'until actual air raid experience' has been gained At the same time we have already some relaxation as to hand torches and masks for headlamps

It seems to me most important that the black out should still be under day to day consideration and should even be subjected to further experiments by the R.A.F The state of affairs in the sky must not be divorced from that on the ground Living in a country district I am perhaps naturally more concerned with the latter at the moment With short days approaching, a certain amount of transport must move after dark For instance our food comes entirely from a big London stores at present on five days a week in future on two Can their staff complete their round in two fifths of the time without risk of breakdown in health of the drivers if the strain of moving after dark is substantial' Similarly, even doctors perform their essential duties' Special care is now needed by day and night on the roads owing to the increase of bicycles in my locality they are sold out There are an additional difficulty to motor drivers Children must somehow or other be fetched from schools Schools will probably close early but my children have to go 5 miles and with reduced train and bus services and a walk of 2 miles at one end and 1½ miles at the other it is going to be a hard job to get them home before dark

At first sight it seems sound sense to tell people to keep off the roads unless they have urgent errands But the morale of the population must be maintained, and people can hardly be expected to be kept in isolation indefinitely from friends relatives and entertainments after the day's work. Some evening family meetings for bridge or even gossip will ease the difficulties of economising in fuel and light (you come to me once a week and vice versa).

I suppose it is impossible to give the harassed householder any standards If he has darkish curtains no shaft of light shows at, say 10 yards you could tell the room was alight behind the curtains but not at 30 Does this really matter' The evenings have to be passed somehow and many people are now trying to read and sew by inefficient light

There is still another point which demands consideration No doubt it was imperative to make householders and the users of cars expert in the prophylactic measures necessary in an air raid but that knowledge having been inculcated (and incidentally all the more light hearted traffic having been ruled out of the running) is there not a risk that the maintenance of strict precautions over a long waiting period will defeat its own end? Will not slackness and carelessness arise? And would it not now be better to relax the code to the understanding that it is instantly and automatically applied in the face of danger' Habit and fatigue are not subjects new to the industrial psychologist Is it not possible that in the work of the Industrial Fatigue Research Board and its successor a useful precedent may be found' If psychologists can answer these questions in advance of actual and possibly painful experience so much the better

I am, Sir, yours faithfully,

COUNTRY GLOW-WORM

Sept. 14

DR CHARLES MILLER

A MEMBER of the staff of University College Hospital writes 'In 1937 our hospital was faced with the retirement of its only remaining physician of mature years The desire to obtain the experience and stability of a senior man was translated into an invitation to Charles Miller to become senior physician for what would have amounted to 3½ years until he reached the usual retiring age It was not expected that his appointment would call for any great effort on his own part and it was hoped that his mature judgment would in itself be sufficient justification for this unusual invitation But Miller proved to be very much more than a mature mind, his drive his personality and his kindness quickly secured for him an affection that could not have been greater had he devoted his whole life to the hospital

"He never missed his ward rounds or outpatient clinics and returned to the problems of teaching with great enthusiasm, his attendance at committees was regular and his opinion always frankly expressed Dr Miller had an almost uncanny habit of scenting out clandestine wrongs, and bringing them into the open to put things right, whether the matter affected nurses, patients or students he could not tolerate anything that was unjust or unkind

'As senior physician in a strange school he may sometimes have felt his position to be difficult, it is to be hoped that he realised to the full the affection which he so quickly achieved of colleagues nurses and students His experience and friendship were freely at the service of all his juniors many of whom have reason to remember with gratitude his help and advice His death has taken from us a much loved man"

DR LEONARD WILLIAMS

Dr AGNES SAVILL writes With the death of Dr. Leonard Williams there has passed away a picturesque personality who will be sadly missed by a large circle of friends and patients The public knew him by his emphatic views on diet and his scathing denunciations of the over athletic and hedonized examples of modern girlhood who neglected the finer qualities of womanhood which he held in veneration He never hesitated to flay his opponents with a peculiarly pungent pen but even his victims enjoyed the perusal of their castigation in witty and beautiful prose He had the artist's appreciation of beauty particularly in the choice of words and phrase in writing and in oratory His naturally beautiful speaking voice added to the attraction of his stimulating conversation and public speeches The latter often given in French and German and always with unbelievable eloquence used to captivate his medical audience Because he lived beyond the allotted span it is now forgotten that he was a pioneer several years before the late war he introduced small doses of thyroid and other ductless glands and became a strenuous advocate of the use of raw and fresh foods What has become a commonplace to-day was advocated by Dr Williams many years before science had heard of the vitamin content of such a diet

PARLIAMENTARY INTELLIGENCE

ON THE FLOOR OF THE HOUSE

By MEDICUS, M.P

THE House has now got into a regular war-routine The Prime Minister makes a weekly statement on the conduct and progress of the war and on this matters of policy come under review by the House Questions also have resumed their place on the order paper, and by means of questions any matter of special or local importance can be brought up and ventilated This is where the art of the supplementary question is displayed, for this can be framed in a way which would not "get past" the scrutiny of the wording which all printed questions undergo. The scrutiny is to make sure that questions come within the rules of order and the rules of the House Broadly, this means that they must be questions addressed to the Minister concerned on matters which are his concern and not, for example, the concern of a county council or a private organisation Great use is being made of the "motion for the adjournment" in order to facilitate debate. It is on this motion that the Prime Minister makes his statements and on which any general matters of policy can be discussed

Opposition in the sense of Party opposition on peace-time lines no longer exists The Opposition has become the constructive critic of the Government's proposals and actions and the guardian vigilantly on the watch against any infringement of civil rights or liberties

* * *

Criticism in the House of Commons is very free and in the last week was expressed with emphasis on two important matters Firstly there was criticism of the Ministry of Information and the censorship whose actions in censoring the publication of the news of the presence of British troops in France—which had been announced to the world at large on the French radio—caused the confiscation of daily papers already printed and quite needless expense, confusion and irritation. The responsibility for this was attributed by Mr. Greenwood, who is leading the Opposition with conspicuous vigour and ability, to the Minister of War, and it is very desirable to have this freedom of criticism and discussion to bring such matters to the light

Another useful discussion was that on the education of school-children and the evacuation of mothers with children under five and expectant mothers to the rural and other reception areas in Great Britain The debate made it clear that the two problems are distinct Speaking generally, the evacuation of children of school age has proved very successful The reception areas have provided for the children very well, the vast majority of them are happy and contented and the minor personal difficulties are being adjusted by that tact and understanding for which the Minister of Health has pleaded in a circular sent to all local authorities

In the debate too much attention was focused on the occurrence of verminous conditions among the children. Unfortunately, in a proportion of school-children for all areas some verminous cases are found Naturally enough, the evacuation of these children has turned a spot-light on their condition, and the unfortunate householders upon whom these verminous children have been billeted have experienced at first-hand the conditions which are bred out of the least well-cared-for stratum of the population. The facts are of course well known to doctors, but they have come as a shock to the dwellers in many pleasant villages and little county towns

A number of cases were mentioned in the House where evacuees had such filthy habits that they used their bedrooms or other rooms in the home where they were staying as a latrine It would be interesting to know how widespread this was and how many cases were actually involved Probably the total number in the county could be counted in tens But why did such things occur? Was it the psychological effect of the uprooting from the town, the journey to a sometimes remote county area, the darkness of the country and the absence of the familiar water-closet—or are the cases of subnormal type? Complaints come from parts of the country as wide apart as East Anglia, Wales and Scotland, but the actual numbers were certainly small

* * *

It is clear that the shifting of population from the towns to the country—and of a predominantly child population—will necessitate the setting up of medical and nursing services and of clinics on a scale unprecedented in rural areas The desirability of a communal mid-day meal was stressed in the debate and by the Minister of Health in the circular sent to local authorities And it was suggested in the debate that this meal should be so balanced as to constitute, with the normal breakfast and tea meal obtained in the billets, an optimum diet from the medical point of view With the larger number of children of the nation in the country areas the opportunity occurs of greatly improving their physique and using the war period as one in which the children of the nation will be brought up under ideal physical conditions The education services in the country will also need to be remodelled, and steps towards that are already being undertaken

One gets from these debates in the House a picture of vast forces at work remoulding the national life If the daily life of the school-children can be put on a sound and healthy basis, as now seems possible, we shall equip the young generation in a way that no whole generation has ever been equipped before. It is true that as at present arranged these optimum conditions, even if established, would cease at 14 or 15 But there is already a good prospect of improvement in the living conditions of adolescents Optimum conditions of these young people also would give a "peace" reserve of a new generation to take up the tasks which will fall to the world when the war is over

FROM THE PRESS GALLERY

Public Health Aspects of Evacuation

IN the House of Commons on Sept 14 a debate took place on evacuation. There was general agreement that the manner in which it had been effected reflected on the whole the greatest credit on all concerned, but there was some criticism of points of detail Mr. EDE mentioned cases where sanitation and water-supply were giving concern to the local authorities Mr. STEPHEN urged that in future the Government should see that each authority evacuating children appointed a responsible official to examine all the billets, and that evacuated children were provided with proper clothing and boots and shoes Captain THORNTON-KEMSLEY said that complaints had reached him that children and their mothers had been evacuated in a verminous condition and inadequately clad. Medical officers and sanitary inspectors should see that people of this kind were

evacuated in a clean state, or else sent into some sort of communal billets Care was also needed to see that where evacuated people made their own arrangements for feeding their children the money provided was actually spent on food for the children He knew of cases where the money had been spent on "red biddy" These people should be given coupons exchangeable for essential foodstuffs instead of money Major OWEN gave details of similar experiences in North Wales In some cases, as a result of the filthy habits of the evacuees, bedding clothing, and even blinds and curtains had had to be destroyed It was hard that there was no compensation for the losses endured by the people in these reception areas as a result of the lack of care and attention on the part of the medical authorities in the city of Liverpool Some of the evacuees had been sent out suffering from scarlet fever, diphtheria, and mumps

Mr COLVILLE Secretary of State for Scotland, said that he would like to believe that none of the stories was true about children being evacuated in an unclean condition, but he was afraid the evidence was that there were a number of such cases Except in the event of serious air-raids and burnings, every possible step would be taken in future to ensure that no child would be transferred to a billet in a verminous condition If it was necessary to remove a child who was not free from infection or disease he was anxious to make arrangements for the reception of such a child into an institution or other place where it could be properly attended to

Dr HADEN GUEST said that anyone who would take the trouble to read the reports of school medical officers in such places as Glasgow, London, Edinburgh, and in fact any town in the country, would find that unfortunately there was always a proportion of children who were verminous On the whole, so far as the unaccompanied school children were concerned, the evacuation had been an outstanding success It was unfortunate if the rooms of houses in the reception areas had been fouled by persons using them as latrines, but the explanation might have been a psychological disturbance due to the evacuation of people to unfamiliar surroundings These were abnormal cases which would be rectified as soon as people got to understand their new quarters and the usages which prevailed in country districts He urged that they should aim at giving every child from the town districts not only a good diet, but the optimum diet laid down by the medical authorities as necessary for the child's development. He had carried out a feeding experiment many years ago and found that it was possible to concentrate the major nutritive foods in the midday meal Boots and clothes should be provided through the school authority and paid for by the parents in instalments

Mr RONALD TREE said that provision should be made for children between the ages of one and five on a nursery-school basis This system was an answer to a great many of the problems arising in homes where parents had not had a chance to teach children habits which they should form when they were very young

Mr MCENTEE said that in Rutland it was impossible to provide for the evacuees free milk and cheap milk and other services to which they had been accustomed in the town areas as from which they came The Government might advise the larger local authorities to transfer their services where they could be effectively used for the children

Mr ELLIOT Minister of Health, said that the evacuation scheme on the whole had been a considerable success, but it admitted that they had had experiences from which they ought to learn In circular No 1871 the attention of local authorities had been drawn to the matter of the inspection of children The Government would do their best to deal with the public health aspects of the case The arrangements for providing evacuated children with medical attendance had been made with the cooperation of the British Medical Association Any householder with whom an unaccompanied child was billeted might without expense to himself, call in a doctor if he thought it necessary The Government felt that the general principle of asking parents to make a reasonable contribution towards these expenses was sound The suggestion that children under five should as far as possible be treated on the creche system, large or small, was one which the Government welcomed and to which they had called attention in their circular

Medical Services

In the House of Commons on Sept 13, in the course of a statement on the war situation, Mr CHAMBERLAIN said that some 200,000 hospital beds had been made available for the reception of civilian air raid casualties These beds, of course, were also available for service sick and casualties and a certain proportion of them were now in use for that purpose It was also a part of their scheme that these hospitals should continue to admit ordinary acute surgical or medical cases amongst the general population This "reflux" was now taking place and would continue Any patient whose medical condition required inpatient treatment should be able to obtain it These cases would naturally encroach upon the number of beds immediately available for the reception of casualties, but that was being met by increasing the numbers of extra beds, by pressing forward with the building of hutted wards, and by providing further temporary accommodation in large tents, so that in spite of fresh admissions the number of beds immediately available had been maintained at the figure of 200,000 Furthermore, they had asked that outpatient facilities for the ordinary civilian sick should be maintained and this was being done The first-aid posts, both fixed and mobile, had been in general duly established and equipped and the emergency ambulances had been assembled and fitted up Motor coaches in the provinces as well as in London had been converted for use as inter-hospital ambulances The full complement of casualty evacuation trains for civilian cases had been assembled and staffed and provided with medical equipment Some shortage of extra beds, bedding, dressings and surgical equipment had been reported from a number of places, but this was being met as rapidly as possible by accelerating the delivery of goods on order, by the diversion of supplies from places more favourably situated and by placing fresh orders In particular, surgical instruments were now being delivered in considerable numbers and others had been obtained on loan from hospitals and surgeons having a surplus available

University Finance

In the House of Commons on Sept 13 Sir DONALD SOMERVELL (Attorney General) moved the second reading of the Universities and Colleges (Emergency provisions) Bill He said that part I applied to the universities of Oxford Cambridge, and Durham, and the colleges and halls within those universities, and the colleges of Winchester and Eton These were the institutions which were dealt with by the Universities and Colleges Estates Act, 1925 Part 2 applied only to the universities of Oxford and Cambridge and to their constituent colleges, and provided for alteration of procedure applicable to those institutions as laid down in the Oxford and Cambridge Act 1923 This bill was similar to an act which was passed in 1916 The result of war conditions on these institutions would be a substantial loss of revenue, fewer students meant less fees and dues Part 1 enabled the various bodies to draw on the future for the needs of the present Other universities had similar problems which would require separate legislation Clause 1 of this bill enabled the institutions to borrow not only the capital charges but also to make good any deficiencies in revenue due to war conditions and clause 2 enabled the period of repayment of existing loans to be extended The bill also empowered these universities and colleges to make emergency statutes

QUESTION TIME

SEPT 13–15

Standard of Accommodation for Evacuees

Mr PARKER asked the Minister of Health whether any general standard of accommodation had been laid down for evacuees in reception areas; and whether children could be removed from unsuitable dwellings—Mr. ELLIOT replied The standard generally observed in billeting evacuated persons is on the basis of one person per habitable room It may have been necessary to exceed this standard as a temporary measure, but redistribution from overcrowded districts is now taking place Local authorities in the receiving areas have been instructed to set up welfare committees to supervise the general welfare of evacuated children and see that they are not left in homes found to be unsuitable

Cod-liver Oil

Mr LAW asked the Chancellor of the Duchy of Lancaster, whether, in view of the evacuation of children and nursing and expectant mothers, steps had been taken to ensure that adequate supplies of cod-liver oil were available in the evacuation centres—Mr W S MORRISON replied *There are ample supplies of cod-liver oil to meet* all requirements, and I understand that the reception areas are obtaining the full quantities they need through the usual channels

Enrolment for National Service

Mr GRENFELL asked the Minister of Labour what steps should be taken by persons who wished to offer their services upon work of national importance, whether paid or unpaid—In the course of a circulated statement in reply Mr E BROWN said that *members of the medical, dental or* pharmaceutical professions should not apply to the Central Register, but should consult the appropriate professional organisations if they desired advice or guidance

Emergency Medical Services

Mr PARKER asked the Minister of Health whether he was aware that there was great discontent in the emergency medical services arising out of the fact that many nurses, medical students, doctors and others were expected to give their services voluntarily or for purely nominal remuneration, and whether he would examine and rectify these grievances—Mr ELLIOT replied No, Sir, I am not aware of any such discontent We have in this country a great tradition of voluntary service to those in need, and those who give such service, whether in peace or in war, are rightly proud of it Standard rates of payments have been arranged for doctors, nurses and nursing auxiliaries *employed wholetime in the service* With regard to medical students, I understand that in general they are most willing to assist in the treatment of casualties, and I cannot believe that they wish to profit by the circumstances of the war

Replying further to Mr. Parker, Mr ELLIOT said that he would undertake to investigate any grievances brought forward

Regional Commissioners

Replying to Sir HENRY MORRIS-JONES, Sir JOHN ANDERSON said The Regional Commissioners have now been charged by warrant with a responsibility of ensuring that the civil defence plans of the government departments and local authorities are properly coordinated Under present conditions they are not invested with specific powers, but they are in a position to use their influence to secure the completion of local civil defence preparations and the smooth working of measures already in operation In the event of a breakdown of communications the commissioners, in consultation with the regional representatives of government departments, will exercise the powers vested in His Majesty's Government until communications have been satisfactorily re established

Sir H MORRIS JONES asked whether the it hon gentleman would assure the House that the present democratic system of local authorities would function until there was lack of communication.

In reply to a further question Sir J. ANDERSON said I understand that the normal system is working, but that it has been most usefully and valuably reinforced by the addition of an emergency organisation held in constant readiness to function in the event of any interruption

The Minister, he added, had an overriding authority over the commissioners.

Sir FRANCIS FREMANTLE Does not the Minister recognise the great confusion arising from the use of the words "Regional" and "Regional Commissioners" when the Minister of Health is always referring to the regionalisation of the Ministry of Health?—Sir J ANDERSON There should be no confusion Regional commissioners have been appointed for the twelve areas into which the country has been divided, and partly in consequence of that plan the arrangements by which the different ministries concerned in civil defence carry out their local functions have been brought into line, so that the Ministry of Health and other departments have a regional representative at the headquarters of each regional commission That makes for the elimination of delays.

Production of Medical Supplies

Mr PETHICK-LAWRENCE asked the President of the Board of Trade whether he would give an assurance that in placing restrictions on normal production he would give sympathetic consideration to all forms of medical supplies and of supplies intended to relieve physical defects, including, in particular, high-tension batteries used in the latest *implements for the deaf*—Mr STANLEY replied It is not possible to give any guarantee as to the treatment of any particular class of goods, but every endeavour will be made to give due weight to every reasonable claim

May I take it that sympathetic consideration will also be given to other parts, such as cords, condensers and other things required for the implements—Yes, Sir

Powers for the University of London

Sir ERNEST GRAHAM-LITTLE asked the parliamentary secretary to the Board of Education whether, in view of the membership of convocation of the University of London exceeding 17,000 graduates, he had considered giving relief by legislation to the authorities of convocation from their statutory obligation of convening convocation for the conduct of elections to the senate and other offices or for ordinary meetings during the present crisis—Mr KENNETH LINDSAY replied A bill is already before the House giving the Universities of Oxford and Cambridge a general discretionary power to make emergency statutes and this power makes possible the suspension of normal statutory obligations *The most convenient way of meeting* the difficulty raised would seem to be that the University of London, perhaps in common with other universities, should seek similar powers

Hospital Treatment of *Athenia* Survivors

Mr ROBERT GIBSON asked the Secretary of State for Scotland how many survivors from the *Athenia* were received into hospitals on arrival ashore, into what institutions they were received, and how many were still receiving treatment—Captain MCEWEN, under secretary, replied 30 survivors were admitted to hospitals in Scotland on landing Of these 19 were admitted to the Western Infirmary, Glasgow, 2 to the Victoria *Hospital*, Glasgow, and 9 to the Royal Infirmary, Greenock Thirteen are still receiving inpatient treatment The Secretary of State would like to express his appreciation of the prompt *measures of assistance carried out by individuals and* public bodies in Glasgow and Clydeside.

Extension of Summer-time

Replying to several questions Sir *JOHN ANDERSON said*: I am not yet in a position to announce a decision If summer-time is to be prolonged beyond Oct 8 the question what should be the terminal date requires careful consideration and inquiry into that question is still proceeding. I hope to be able to make an announcement shortly

IN ENGLAND—NOW

(FROM OUR PERIPATETIC CORRESPONDENTS)

HAPPENING to Guy's yesterday I found many garden games going on in the "Park." Much of this has been converted into an elaborate fortification and the engineer may be commended for his power of improvisation. Some time ago he built a new chimney for the works, and had the old one, an iron tube, lying in the yard. This was in sections which he unbolted and cut each section longitudinally. He then had his trenches dug six feet deep and of such a width that his half tubes fitted on the top. When these were in place earth was piled on them and sandbags fitted over all to prevent the earth loosening. The entrances were then improved with further sandbags. All this kept the boys pretty busy for a week, but it is now finished. It is, I believe, lit by electric light, but I do not think they have allowed for urinals. I fear that with youths of both sexes in their night attire the ground may become fouled with moisture, if the old phrase for the condition in which we are when awaiting our Final exam is a true description of the physiology of fear. I believe it is in the Good Book, but a hasty glance through my Cruden does not enable me to put my finger on it.

So *The Lancet* has gone to Aylesbury. My only visit there was by bicycle from Hampstead in 1898—it was 80 miles and I was whacked at the end of it. Now slips of girls do 120 in a day, I believe, and do not turn a hair. I suspect it is the road surface, but the bicycles are also lighter, higher-geared, many-geared and have free-wheels. I remember Aylesbury on market day as the sleepiest old country town I have ever seen—except perhaps Wantage. I suppose the war has changed all that.

* * *

Oxford in war time sets one wondering. Balliol and Christchurch have large yellow notices outside announcing that they are air raid shelters, while behind boards the new Bodleian, just out of its scaffolding, reminds us of the things we used to think worth building. I suppose there are reasons which justify smashing up all the lovely things in this world, but here they seem very remote and rather inadequate. Oxford always reminds me of the Old Town at Frankfurt, where I've spent so many happy days. I don't quite see how a tit-for-tat argument with bombs (you smash our Magdalen, we smash your Römer) does advance the political organisation of humanity. If both sides can and do confine themselves to pamphlets and military objectives, in the gentlemanly way they have done so far, war may yet become a civilised occupation for those who like it. I suppose the real trouble will begin when one side starts to get the worst of it.

* * *

To get back to Oxford, and in particular, the Radcliffe. There, evacuation of convalescents has been followed by an influx of London evacuees. The neuro-surgical department is as busy as ever—everyone seems to want to get their skulls cracked by Mr Cairns before bombs do it for them. Each month Oxford is being called upon to find accommodation for 200 London women in their last days of pregnancy. Some of them are in the fine new maternity block at the Radcliffe, some in Ruskin College, some in Lynsham Hall and some in the new casual ward at Kidlington. After delivery they are either to be billeted in the district or returned to London. When the Thomases and Guy's students are to stay when they arrive at Oxford I don't know.

* * *

The Radcliffe also accommodates the extremely efficient municipal cleansing station. Cleansing these days in anti-mewing mustard gas rather than bugs or scabies. In an outer chamber the outer garments of the contaminated are removed. Then the sheep are separated from the goats—the males into one stripping-room, the females into another. Each then passes through a double row of showers, in the middle of which are arrangements for eye douching. Finally, fresh clothes are provided and the fortunate decontaminees of Oxford emerge from a common door, regardless of sex.

* * *

A great many people are hoping or fearing that the Ministry of Health's emergency medical service is the beginning of *state medicine*. The shower of criticisms which it is at present receiving would not perhaps have burst if the expected cataclysm of bombs had descended on London. As it is, a great many doctors are twiddling their thumbs and thinking about their salaries. The only people who seem to be completely satisfied with their share of the new national debt are the house-officers, who receive from a benevolent Government the princely wage of £350 a year plus an extra £100 if living out. This is about £350 a year more than most of them have been accustomed to receive. The higher doctors, if ranking as specialists, bag £800 a year, while if classed only as medical officers they must be content with £550 a year. A few chosen individuals in charge of whole hospitals pass the thousand mark. In the old days of voluntary hospitals and honorary staffs, a man could hope to make £1000 at 35 even if he was one of a staff of perhaps forty honoraries. In the new scheme of things that privilege appears to be reserved for one member of the hospital staff only. Not unnaturally the seniors think it would be a good thing to dock some of the house-officers' salaries to augment their own. And it must be admitted that there is something in the argument. The young man recently qualified living in residence has no expenses beyond his clothes, an occasional hair-cut, and a sports car. With petrol rationing even the sports car is redundant. The older man with a wife, a house or flat, a room in Harley Street and a couple of sons at a public school can look forward only to an increasing burden of personal debt in the service of his country. At the same time, the case for paying the house-officer a reasonable salary is a strong one. In the past those of us who were unfortunate enough to have no private means have been thankful that resident appointments left little free time in which to study our poverty. The London voluntary hospitals have traded on the value of resident appointments to get cheap labour and only in the provinces have most house appointments been paid. The Ministry has at least put a stop to this exploitation of the youth. One only hopes that it will also find some way of doing justice to age.

* * *

Two workmen were sitting opposite me in the train discussing the war. One of them said, "When I get home at night I always switch off the jazz on the wireless and tune in to a German station. I don't hate the Germans, they make such tuneful music."

' I think the day is coming when we shall stop talking about 'mental disease' and 'physical disease' because I am convinced it is an artificial and wrongful separation. The human organism becomes ill, and one cannot separate the human organism into separate entities any more than one can consider it apart from its environment. I say the distinction is an artificial one because it was thought that dementia paralytica was a 'mental disease' and then was discovered to be caused by the spirochete. Does it now become a physical disease with mental symptoms? It may be demonstrated that there is scarcely a physical disorder that doesn't have its mental concomitants—a carbuncle on a patient's neck has a definite influence on his personality.' More difficult, perhaps, but just as logical is the assumption that there is no so-called mental disease that does not have its physical concomitants which may ultimately be demonstrated. (CHARLES BURNHAM, *J. Amer. Med. Ass.*, July 29, 1939, p. 379.)

OBITUARY

FREDERICK SPENCER LISTER

KT, M R C S, LL D CAPETOWN

Sir Spencer Lister, who died at Johannesburg on Sept 6 at the age of 63 had been director for the last fifteen years of the South African Institute for Medical Research. He will be remembered as one who boldly applied the principles of immunology on a large scale to the needs of the community For some time past he had suffered from the strain of constant diligence, and it was a heart attack which ended his life suddenly in the library of the institute.

Frederick Spencer Lister was born at Norwell, Notts, and after a private education he entered St. Bartholomew's Hospital, where he qualified in 1905 Two years later he went out to the Cape as medical officer to the Premier diamond mines, spending five years there before going on to the Rand gold mines at Johannesburg. One of the gravest problems of the gold-mining industry was then the high death-rate from pneumonia amongst the native labourers After a favourable trial by A J Orenstein of active immunisation with pneumococcal vaccine, Lister was entrusted with the task of doing a grand-scale experiment in preventive medicine In those days little was known of specific bacterial antigens Lister typed the South African pneumococci, working concurrently with the American bacteriologists who were then attempting to classify them, but, it should be added, quite independently Some may regret that the American nomenclature was retained rather than Lister's In this great experiment Lister had not the advantage of knowing what part in pneumonia was played by associated bacteria, nor had he the opportunity of statistical planning. Certain it is that the death-rate from pneumonia among the native labourers dropped sharply between 1916 and 1920, concurrently with the mass inoculation But it must not be overlooked that from 1911 on the recruitment of tropical natives had ceased and improvement had already set in For this work Lister received a well-earned knighthood in 1920 Four years later he succeeded Dr Watkins-Pitchford as director of the South African research institute and became president of the associated scientific and technical societies of South Africa When the University of Witwatersrand came to include a complete medical school Lister was appointed honorary professor of pathology and bacteriology, the actual teaching being delegated to members of the staff of the institute, an arrangement which served well to keep the school and the institute in close touch. From 1928 he served on the South African Medical Council, and in the following year the University of Capetown conferred upon him the honorary degree of LL D.

The impression Lister gave on his co-workers was that of a keen and critical worker with a true interest in research A man of personal modesty, he was well liked by those who came in contact with him and valued his simple forthright character His laboratory gifts, as befitted a pupil of Almroth Wright, were of a high order They were on the technical side rather than in the imaginative field, and it may be for this reason that one of the largest human epidemiological field experiments failed to give as much information as it might have done Outside his devotion to laboratory medicine Lister had few interests apart from sport.

Sir Spencer Lister was twice married His first wife, who died in 1919, was the daughter of Leonard Baker In 1921 he married Ruby May, younger daughter of W P Johnstone of Durban, who survives him with a son and a daughter

NEW ZEALAND

(FROM OUR OWN CORRESPONDENT)

NATIONAL HEALTH INSURANCE

THERE is no further development in the national health insurance scheme. The government has been occupied with the budget, which includes considerable increases in taxation, particularly on income and petrol The Prime Minister has just been operated on, the Finance Minister is still abroad and the Health Minister has been acting as prime minister in addition to his other duties A revised scheme for maternity services, including provision for extra payments for complications and consultant services, without any contract between doctors and government, is under discussion. It is being voted on by members of the B.M A by secret ballot, and the results are not yet published. It was announced before the ballot that the government had accepted the scheme in principle

STAFF CHANGES AT AUCKLAND HOSPITAL

Eighteen months ago the board created two new full-time posts at Auckland Hospital, the chiefs of the divisions of medicine and surgery, at salaries of £N Z.1500–2000 There was no consultation with the honorary staff about this step, but when Dr. C. R Burns and Mr J M Clarke were appointed, it was on the advice of a wide and representative medical committee. This feature made the occasion noteworthy Never before in medical appointments had any expert advice been properly sought, much less acted on These reforms were part of a larger scheme, planned to include the abolition of the post of medical superintendent, and were intended to introduce more order and responsibility on the clinical side Certain influences were brought to bear, and the post of M.S. was not abolished The two appointees arrived after some months, to find their powers already diminished on paper. A change of board (elected by popular vote every three years) confirmed their impression that they were not really wanted, and after about a year of office their appointments were terminated on the score of economy Only one member (a junior physician) of the honorary staff has recorded publicly a protest against such summary dismissal of two eminent men The profession has been silent, but considerable public protest has been made, including a petition from the bulk of the in-patients, and another from a large majority of the nursing staff. By these it was claimed that since the men had arrived the general tone and morale of the hospital had improved, and that gaps in the work of the hospital left by the honorary system of staffing had been filled. While it is clear that most of the senior members of the staff desired the abolition of the posts, there is a section of the middle and junior group in the city that deplores the move. These see in it a setback to proper coördination of the clinical work, and to the introduction of academic standards into the appointment of the honorary staff.

UNIVERSITY OF OXFORD.—The appointment of a deputy to carry on the duties of Dr. Lee's professorship of anatomy has been cancelled, as Prof. W. E. Le Gros Clark, F R.S, has withdrawn his resignation from the professorship.—Dr. K. J. Franklin is deputising for Dr. B G Maegraith as dean of the medical school.

Medical News

General Medical Council

An election is about to be held of one member of the General Medical Council to represent the registered medical practitioners resident in England Nomination papers, which must be signed by not fewer than twelve registered medical practitioners, must reach the registrar before Oct 3

Royal Cancer Hospital (Free)

The course in physics and medical radiology to be held at this hospital will begin on Oct 3 as arranged Further information will be found in our advertisement columns

Radium

The National Radium Commission has indicated that radium treatment is likely to prove impracticable in the earlier stages of the war and centres have taken steps for the continuous storage of their radium underground According to *The Times*, most of the national stock has been buried in a 50 ft bore hole drilled specially for the purpose When more experience of war conditions is available it is hoped that it may be possible to resume treatment Correspondence for the Radium Commission should be addressed, until further notice, to the office secretary at 18, Park Crescent, London W 1

EMERGENCY NOTICES

The annual meeting of the British Medical Association which was to have been held in Birmingham next year will not take place

The annual conference of surgeons of the St John Ambulance Brigade, which was to have been held in London on Oct 14, has been cancelled

The course of lectures on neurology which was to have been held at the National Hospital, Queen Square, London, this autumn will not take place

No meeting of the Society of Public Analysts and other analytical chemists will be held until further notice

The St Marylebone and Western General Dispensary is open for outpatient treatment only and a list of the clinics which are carrying on may be had from the secretary of the hospital, 48, Cosway Street London, N W 1

The British Hospital for Mothers and Babies, Woolwich, has received permission to retain all its 52 beds for the use of women in and after labour Although already fully booked for the next seven months it has undertaken to receive all the maternity patients from the Garrison Maternity Hospital and the War Memorial Hospital, Woolwich

Of the 60 beds at the Plaistow Maternity Hospital 40 have been vacated, the remaining 20 are being used for emergency and abnormal midwifery cases Many of the expectant mothers of the district have been evacuated and several midwives have gone with them but there are still a great number who have refused to leave and the majority of these will have to be confined in their own homes by the midwives attached to the hospital

The Chadwick public lectures which were to have been delivered this autumn have been postponed for the present Notice will be given when they are to be resumed

For the duration of the war the head office of Messrs Watson & Sons (Electro Medical) Ltd will be at 7b, Castle Street, Reading (Tel Reading 60295 telegrams "Skingrain Reading) Their London office and all branches, with the exception of Glasgow, will remain open for sales and service

The King's College Hospital annual dinner of past and present students has been cancelled

Mrs BURDEN benefactress of the Stoke Park colony, Bristol has died Her husband the Rev Harold Burden founded the colony and after his death she continued to live there her last gift being the neurological institute which was opened by Sir Thomas Inskip on May 12

Appointments

BRASS SYDNEY assistant physician to the skin department, St Paul's Hospital, Endell Street London

BRODY, M B , M D Sheff D P M senior resident physician at the Runwell Mental Hospital Wickford, Essex

CLAYTON, T M , M D Durh , D Hy D P H , D T M , medical officer of health for Blaydon on Tyne

HAMILTON, BETTY C L R C P E , L D S R C S F D P H , assistant school medical officer for Derby

JACKSON, D C M B Melb resident medical officer at the Birmingham Children's Hospital (King Edward VII Memorial)

MACFARLANE G N , M B Dubl , resident surgical officer at Birmingham Children's Hospital (King Edward VII Memorial)

MATEER MARY H M D Lond F R C S , M R C O G , obstetric assistant and tutor at the Liverpool Maternity Hospital

PEMBERTON, MAX, M B N Z F R C S , surgical registrar at the Aberdeen Royal Infirmary

SUTHERLAND, CATHERINE M M B Edin , resident medical officer at the Jessop Hospital for Women Sheffield

WATSON, A J , M D Durh , B Hy , D P H medical superintendent at the Mildmay Mission Hospital, London

Examining Surgeon under the Factories Act, 1937 Dr J G CLARK (Dundee district Angus)

Medical Referee under the Workmen's Compensation Act 1925 Mr H W GABE F R C S for the county-court districts of Haverford West, Pembroke Dock and Narberth

Births, Marriages and Deaths

BIRTHS

CHANCE.—On Sept 14 at Dublin the wife of Dr Oliver Chance —a daughter

FORSYTH.—On Sept 15, at Royal Naval Air Station Winchester the wife of Surgeon Lieut -Commander V S Forsyth—a son

PARKER.—On Sept 16 at Oxford, the wife of Mr A S Parker D Sc —a daughter

STEPHENS.—On Sept 10, at Srinagar Kashmir, the wife of Captain L R Stephens R A M C —a son

WILKINSON.—On Sept 11, the wife of Dr M C Wilkinson of the Essex County Sanatorium Black Notley—a daughter

MARRIAGES

BIRT—HUSBAND.—On Sept 15, Alan Beckett Birt M B to Joyce Staunton Husband

CHAMBERS—STEVENS.—On Sept. 9 Captain Alfred Chambers, R A M C to Susanna Ruth Stevens

COOMBS—BLAND.—On Sept 9 at Bristol Charles John Franklin Coombs M B to Barbara Bland

CUTTING—MASTERS.—On Sept 15 at Wimbledon Park, Alfred Howard Cutting M R C S to Margery Masters B Sc

JONES—STRONG.—On Sept 9 at Ilsley Church William Alyn Jones M R C S , to Doris Whitley Strong

PAGE-CROFT-PIERNOV.—On Sept 9 at Claygate, Ernest Donald Page M B , to Isobel Margaret Torrance Stephenson

VAN MEURS—WYKES.—On Sept 11 at Kingswood Dennis Peter van Meurs M B to *Marjorie Norah Wykes*

WEST—FLEMING.—On Sept 7, at Ardee, Eire Robert George Hayward West M D M R C P to Jean Edith Fleming

WYKES—MITCHELL.—On Sept 15 at Leeds Peter Hitchcock Wyon M B to Agnes May Mitchell M B

DEATHS

HONEYWILL.—On Sept 17, Laurence John Honeywill F R C S , of Bournemouth

JOHNSTONE.—On Sept. 17 at Preston, Thomas Johnstone M D Edin , M.R.C.P late of Ilkley and Harrogate aged 86

KENNEDY.—On Sept 12 at Bucklebury Common Berks David *Kennedy M B Lond*

LOCKETT.—On Sept 14 Gerard Edward Lockyer, M R C S of Houghton Norfolk late captain R A M C

ROBINSON.—On Sept. 16 at Glasgow Harry Watt Robinson M B Glas of Bridge of Weir

WILLIAMS.—On Sept. 14 at Horsham Alfred Henry Williams M D Edin aged 75

The Lancet 100 Years Ago

September 21, 1839, p 932

From a leading article on the case of the Apothecaries Company v Greenough

The public will be the greatest sufferers by the anarchy of the medical profession The lives lost by murder, manslaughter, lightning, precipitation from monumental columns, hydrophobia, explosions in mines shipwreck and accidents of every kind, will be inconsiderable when compared with the numbers that must perish legally, on one hand by the injudicious administration of poisonous drugs and on the other by the absence of the skilful well-directed, energetic treatment of the scientific practitioner

NOTES, COMMENTS AND ABSTRACTS

FILMS FOR DOCTORS

THE world we live in has sharpened our eyesight perhaps at the expense of our hearing The teacher of today realises that many of his pupils are more sensitive to visual than to auditory impressions and he neglects no medium that appeals to the eye The film as an auxiliary in medical education, and especially in postgraduate medical education, was discussed by Dr. E Kittler at a recent meeting of the Berliner Medizinische Gesellschaft (*Disch. med. Wschr.* Aug 4, 1939, p 1242). One of the most obvious uses of films is to show the doctor minor surgical procedures which he may use in his own consulting-room. Films of major surgical operations are also of some value to the postgraduate Such films should not be overloaded with detail, but should concentrate on general methods and end-results. In obstetrics and gynæcology the film can to some extent compensate for the scarcity of clinical teaching material available to postgraduates Medical subjects do not at first sight seem appropriate to illustration. Kittler suggests, however, that if we were less shy of using trick photography there is a wealth of material waiting to be used. An article by Rosenthal in our own columns (1938, 2, 340) describes some ingenious methods of graphic instruction that might be embodied in cinematography.

DEARER DRUGS

THE wholesale prices of the following drugs have increased substantially: tannic acid, ephedrine, phenazone, sulphanilamide, atropine, ergot of rye, cascara sagrada, gentian root, tragacanth, gum acacia, agar agar, aloes, ipecacuanha, hydrastis, rhubarb, menthol, senega root, colocynth, cod-liver oil, olive oil, eucalyptus oil, peppermint oil and aniseed oil. Some of these—tannic acid, ephedrine, cascara sagrada and ergot of rye—have doubled in price There has been a further advance in the price of bismuth carbonate, while makers of resublimed iodine, iodoform, potassium iodide and sodium iodide have, as anticipated, raised their prices to correspond, more or less, with the increase in the cost of crude iodine noted last week The prices of calomel, corrosive sublimate and other salts of mercury have not been advanced as yet, but in view of the rise in quicksilver, higher prices for these drugs are likely. Potassium bromide, as well as other bromides, is dearer Although the official price of quinine has not altered, this as well as chloral hydrate should be dispensed with caution. A rise in the price of camphor is almost inevitable for the reason that turpentine, the key to synthetic camphor, is twice the price it was before the war: competition from synthetic camphor has kept low the price of the Japanese natural product These notes may serve as an indication to prescribers

A LOCAL USE FOR TESTOSTERONE

Mr. J. R Groome, of the department of zoology and comparative anatomy at Oxford, informs us of the successful use of testosterone propionate as a local application in the case of a uniparous woman of 33 who had difficulty in attaining an orgasm during sexual intercourse. Her external genitalia were normal except that the clitoris was so small that she was unaware of its existence An ointment containing testosterone propionate was introduced into the preputial sac with a small syringe twice daily, beginning at the end of one menstrual period and continuing until four days before the next The patient received approximately 6 6 mg. testosterone propionate by unction in seventeen days, the doses increasing as the treatment caused a slight enlargement of the preputial sac. A considerable increase in the clitoris was then reported, and the treatment was resumed for a further five days after the next menses The preputium was now found to be enlarged, and the glans clitoridis, which had drawn the frenulum with it, was normally just visible A month later the preputium had regressed to almost its normal size, but the clitoris and frenulum however had been maintained, and the resulting new erogenous zone was considered highly satisfactory. Mr Groome concludes that "rather less than 7 6 mg testosterone propionate administered by local unction over a period of twenty-two days will cause enlargement of the human clitoris without affecting the other genitalia or delaying the menses"

HANDWRITING

GRAPHOLOGY has been much exploited by charlatans in the past and for this reason has come to be associated in the public mind with the occult It is regarded far more seriously on the Continent than in England, and there are recognised courses on the subject in several European universities In his "Analysis of Handwriting" (London Geo Allen and Unwin, pp. 232, 7*s* 6*d*.) H J. Jacoby treats graphology as a science and interprets his results on an accurate psychological basis. The reader will have no difficulty in following his easy style but must not expect to be an expert graphologist when he has reached the last page. If Jacoby's remarks on illegibility are true, most doctors fall into the category of neurotic people wishing to conceal their weaknesses from the world.

LIGATURES

Mr T. E H Roberts, F.R C S, writes "On my visits to numerous hospitals in the London sector I find that in some cases there is anxiety about the stock of catgut for ligatures. While I am assured by the Ministry of Health that adequate stocks are held in the country, there may be here and there a lag between demand and supply . Under these circumstances may I suggest that fine linen thread, silk or sewing cotton may replace catgut for the ligation of vessels ? In fact these substances in many respects have an advantage over catgut No. 100 thread and No. 24 cotton which are obtainable from any draper are suitable, though many other sizes are also useful. In the same way linen thread or silk, preferably black, may replace silkworm gut for skin suture."

Vacancies

Barnsley, Beckett Hospital and Dispensary —Cas O, £250
Belfast Mental Hosp —Asst M O, £350
Brighton, New Sussex Hospital for Women, Windlesham Road — H P at rate of £100
Burnley County Borough —Sen Asst M O H, £800.
Doncaster Royal Infirmary —Orthopædic H S., at rate of £150 Also H.S at rate of £150
Dudley, Guest Hosp —H S, £150
Dunedin Hosp, New Zealand —Radiotherapist, £1100
Kettering and District General Hosp.—Jun H S, at rate of £150
Macclesfield, Cheshire County Mental Hosp, Parkside —Asst. M O, £350
Manchester Northern Hosp —Hon Surgeon
Reading, Royal Berkshire Hosp —H S, H P, and Cas O, each at rate of £150
St Helens County Borough —Temp Asst M O H for Tuberculosis, £600
Stafford, Staffordshire General Infirmary —H S, £175
Stockport Infirmary —Res Surg O, £250
Watford Borough —Temporary Asst M O H, £600
Medical referees under the Workmen's Compensation Acts, 1925, for the county-court districts of Holywell Flint and Mold (circuit No 29) Also ophthalmic specialist medical referee for the county-court districts of Accrington Blackburn and Clitheroe, Blackpool, Chorley, Lancaster and Preston (circuit No 4) Applications for these appointments to the private secretary, Home Office, Whitehall, London, S W 1, before Oct 8
Medical Referee under the Workmen's Compensation Act, 1925, for the Kirkcudbright sheriff court district (Stewartry of Dumfries and Galloway) Applications to the private secretary, Scottish Office, Whitehall, London, S W 1, before Oct 8
The Chief Inspector of Factories announces the following vacancies for examining surgeons Lander, Berwick; Carnforth, Lancaster; Morpeth, Northumberland.

ADDRESSES AND ORIGINAL ARTICLES

PERSONAL AND CLINICAL HISTORY IN HÆMATEMESIS AND PERFORATION

BY DANIEL T. DAVIES, M.D., B.Sc. Wales, F.R.C.P.
PHYSICIAN TO THE ROYAL FREE HOSPITAL, LONDON, AND
A. T. MACBETH WILSON, M.B., B.Sc. Glasg.
PHYSICIAN TO THE TAVISTOCK CLINIC, LONDON

EXPERIMENTAL stimulation of the hypothalamus or its nervous connexions with the stomach can produce changes in the motility and secretory activity of the stomach. Continued stimulation causes erosions of the mucosa and demonstrable hæmorrhage (Beattie 1932, Heslop 1938). An increasing amount of clinical evidence is now available to support these experimental observations (Alvarez 1932, Cushing 1932, Davies 1936). We have already drawn attention (Davies and Wilson 1937) to the nervous influences which appear to operate in certain personality types in precipitating ulcer symptoms and in determining recurrences. Disturbing situations and events, acting as precipitating factors by causing anxiety to the patients, were found to precede the onset or return of symptoms in 84 per cent. of 205 patients with peptic ulcer and in 42 of 52 radiographically proved recurrences. Comparisons were also made between two matched groups of ulcer and hernia patients. Using the latter as a control group, we found, for example, that unusual psychological tension, as shown by inability to rest, was a lifelong characteristic of 78 per cent. of the ulcer patients but of only 15 per cent. of the hernia patients. Further, external events of a potentially disturbing nature preceded the onset of symptoms of hernia in only 22 per cent. of the patients.

It was thought desirable to investigate the related problems of hæmatemesis and perforation and to record in identical manner observations made both on the predisposing factors which long antedated gastric symptoms and on the external events which preceded the catastrophe. The observations were made on 50 patients recovering from a hæmatemesis and on 25 convalescent from an operation for a perforated ulcer. Bleeding into the stomach may take place as a complication of such conditions as portal obstruction, blood diseases, and carcinoma, but its commonest cause is erosion of the gastric mucosa through acute peptic ulceration or as a complication of the chronic stage. The clinical course and rapid recovery of our group of hæmatemeses were such as to exclude these other pathological conditions. All the patients were examined by methods previously used to record, in brief outline, the characteristics of the individual before the onset of gastric symptoms and to obtain a dated clinical and a dated personal life-history of the individual.

Hæmatemesis

In the 50 patients examined it was found that definite psychological characteristics of two overlapping types antedated the onset of the gastric symptoms. These findings are recorded separately (Wilson 1939*a* and *b*). Of the 58 hæmatemeses these patients collectively suffered 47 were preceded by some alteration in their lives, of a type particularly capable of producing emotional stress. The precipitating events classified themselves most readily in relation to money matters, to the nature of their work, and to serious illness of near relations, with a small residue of miscellaneous disturbances.

EVENTS RELATING TO MONEY MATTERS

CASE 1.—A quiet and rather shy man, aged 22, with a squint, who left home at 18, with his five brothers and sisters, because of quarrels with his stepmother. Since that time he has suffered from restlessness and passing morning depression. Immediately after leaving home he was in hospital for a year with "pains in all my joints." Indigestion began six months after his discharge from hospital and a few weeks after he lost his regular employment. While unemployed he was admitted to hospital and treated for dyspepsia. Eventually he found "unofficial" work in a canteen. Again he lost his job and was for three weeks idle. Of his last unemployment benefit of *7s. 8d.* he gave *5s.* to his landlady, to whom he was in debt. On the next day he could only afford one small meal of fish and chips, and the following day he was admitted to hospital with hæmatemesis.

CASE 2.—A married man, aged 59. "I'm always pottering about doing something, if I sat still for five minutes, that'd be a miracle. I'm not nervy or highly strung, as I understand it, but I think perhaps I worry a bit. I never talk much. I swallow things and it's worse than getting rid of them. I'm inclined to swallow things and sulk about them." He has one boy at home, aged 26, one in the army, and a daughter married two years ago. Since the war he has kept a coffee stall. Indigestion began in 1929, at a time when "trade" began to fall off. In 1934 he failed in business and had his first "bleeding" a few days afterwards. His dyspepsia recurred and a second bleeding took place on the day his daughter married. At this time his son was out of work, he himself had only occasional odd jobs, and her departure made a big difference to the family income. Lastly, he "got extra work at the post office at Christmas time." "Although I was feeling *a bit run down, I didn't* refuse because I was glad of a bit of money. I finished on the 24th of December. My wife took to bed on the 25th with a bad leg that keeps her pretty low. She was fairly ill this time. She was *at my daughter's and I didn't* know how to get her home, so I kept running backwards and forwards. My last two teeth were taken out just before Christmas and that upset me." On Jan. 2 he had his third hæmatemesis. "*Whenever things* get to a climax this happens. As soon as it is over I'm up and all right again."

CASE 3.—A woman, aged 63, the youngest of eighteen, apparently cheerful with six children, all of whom are married. "Nothing moves me—I can't feel frights. Always been active and cheerful—it doesn't do to sit about and mope. Anyway I couldn't sit down for long. It kills me to be in bed." Since coming to London four years ago—her husband came from Wales to try to get work—she has had more headaches than usual and "a little indigestion with the different water." Her husband, aged 65, has had heart attacks. Since March, 1937, he has been out of work, and the doctor told her that his heart "may take him at any time." "Round Christmas, things were tighter than they've ever been since we've been married." Although now 63 years old, she had no indigestion at that time—"only a little lump in my side." On Jan. 3, 1938, she felt a little giddy but did not tell her husband. They "talked till it was gone twelve. I felt sick, and then brought up a lot of blood."

CASE 4.—A woman, aged 57, eldest girl of five children. She has had indigestion as far back as she can remember. It became worse in 1927, when she was worrying about her daughter for "we set her husband and her up in business with our savings and it became a white elephant. He's turned out no

good." In 1931 an appendix was dealt with successfully, but her indigestion was "still just as bad." In May, 1935, she had a nervous breakdown as a sequel to a quarrel with her son, who "had got on very well indeed." Three weeks before her husband's retirement on a pension she had a hæmatemesis. "My husband's retirement made a big difference to us—all our money went in my daughter's business."

The four examples quoted, two men and two women, indicate the close correlation we have noted between certain personality types, financial stress, and hæmatemesis. In the young man of 22 his first and only hæmatemesis took place at a time when his insecurity was at its maximum. Case 2, an older man of 59, had already suffered a good deal in disappointments, and his three bleedings coincided with episodes of some magnitude to him. Case 3, an active restless woman of 63, was worse off financially (and her husband afflicted with a heart "that might take him at any time") than she had been since her marriage, and after a discussion on the state of her affairs "till it was gone twelve" she vomited blood In case 4 the retirement of the husband, with the savings already gone, made the future uncertain, and three weeks before he resigned his work this nervous woman of 57 suffered her first bleeding In all, 16 of the 50 patients disclosed such stories of money difficulties preceding gastric hæmorrhage; 10 of the 16 were persons over 50 years of age, a time of life when security is all the more prized The stories relate to people of poor circumstances, where a few shillings make the difference between distress and relative comfort, but we have not found any difference in people whose finance may be of larger dimensions, as shown by the following example

CASE 5.—A man, aged 56, had suffered from dyspepsia for ten years; numerous radiological examinations had disclosed a duodenal ulcer, and the usual remissions followed upon courses of treatment. During one of these courses of treatment, and at a time when he was already symptom-free, he was awakened from sleep feeling faint and sick. He was found semiconscious by his butler in the early hours of the morning, having attempted to walk to his bathroom. He showed all the signs of severe hæmorrhage but it was some time before the inner history was disclosed. For the first time in his life hæmorrhage had occurred and this to a severe degree. It was also disclosed that for the first time in his life his good name had been doubted and, to redeem his name in the eyes of his bankers, he had to find a sum of £15,000 within a few days. This demand was made to him three days before the hæmorrhage.

INCREASE OF RESPONSIBILITY

CASE 6.—A man, aged 32, an only son, with children of 2 and 3½, formerly an exhibitioner, next a university lecturer, and now a sales manager, describes himself as "nervy and irritable, very ambitious, to be honest," "unable to settle easily to a book," and "rather inclined to get worked up about things" He "had endless trouble with my throat as a child," "disease of the knee," "appendicitis at 11." "My development was held up through always being ill." Indigestion began in 1923 (patient 17) "just before going to the university" (this meant coming to England from abroad), got worse when he finished his studies in 1927, and, after disappearing for "nearly a year," came on again in 1928, when he became lecturer in another university. He returned to his native country to go into business and after a year (1930) had severe pain shortly after his duties had become onerous. Treatment relieved the symptoms and he got married. "Shortly" after his return to business symptoms began once more. He bore it for some time but was eventually advised to leave home and come to Europe for an operation (1932). On his first night aboard ship he had his first hæmatemesis. He had a Billroth II operation and was free of symptoms until he had a hæmatemesis in "the first week in August," after the birth of his first child in July, 1934. Again he improved till January, 1936, when his second child was born, and his pain returned once more. In March of that year there occurred the first of two financial crises in his business, and in April he had his third hæmatemesis. This was preceded by a running nose and a cold, which did not, however, keep him from business. Again he improved until, in August and September, 1937, there was further difficulty in business, and on Sept. 28 he had his fourth hæmatemesis. He had "never noticed" the relation between the events in his life and his dyspepsia.

CASE 7.—A sea captain, aged 58, had enjoyed excellent health throughout his life at sea and prided himself on his digestion, although his facies showed all the features of the classical ulcer patient. Within recent months he began to suffer hunger pains and found that they were relieved both by food and by alkalis. These symptoms came on at sea when some difficulty was experienced in repairing an engine fault of his 14,000-ton and fully laden ship. Within scheduled time the cargo was duly landed at a foreign port While the last of the cargo was being taken on dock he vomited blood. After a stay in hospital he returned to England and was given charge of the boat again. Within twelve months, on landing another load of cargo (this time in an English port), he suffered another hæmorrhage. His story is interesting. Apparently before rearmament days ship engineers were available and any breakdown was adequately dealt with by a competent staff. Now there are better posts on land, and in his ship there was a deficiency of skilled engineering help. The fault that developed on the high seas was, to his knowledge, only patchily dealt with, and he knew that to negotiate the straits to the foreign port necessitated all hands and no engine breakdowns. Any delay in the straits might result in the total loss of the ship and endless inquiries. He was intensely anxious. The hæmorrhage followed on this anxiety. His second hæmorrhage took place in similar circumstances.

CASE 8.—A young woman, aged 25, employed in a children's home, without warning vomited a large quantity of blood in August, 1937. She had enjoyed good health previously and has remained well since. The story is simple. She entered the children's home as a help when aged 17. She was ultimately recognised as reliable, and more work and responsibility were placed on her shoulders In August, 1937, the matron was on holiday and the home was under the charge of the only sister in the establishment. This sister was taken ill suddenly, and the young woman found herself in sole charge. The bleeding took place at this time

CASE 9.—An accountant, aged 40, had a gastroenterostomy performed for a perforated duodenal ulcer in 1927. A hæmatemesis took place in 1933, and radiological examination at a later date showed that he had a jejunal as well as an active duodenal ulcer. In 1934 a lateral anastomosis was performed, for one of the jejunal loops was dilated and partially obstructed. With the correction of this mechanical fault the patient improved. A further X-ray examination, performed a month after the operation, showed no delay in the loop. The patient affirmed that he had never felt better, and he went back to work after a brief holiday. On his return he received "the biggest shock of his life," when his partner demanded dissolution of the partnership because the patient had been away from business too often and too long. Seven days later he suffered a hæmatemesis.

From the time of his recovery until 1938 he did reasonably well. Symptoms of dyspepsia recurred, and many medical opinions were sought. In May, 1938, he was influenced to submit to a gastrectomy as the only permanent cure of his trouble. He was

informed that this would also protect him from further hæmorrhage The gastrectomy was performed, and after a short convalescence the patient returned to work. In August he was away on holiday with his family His three children were taken ill at the hotel, and, at the same time, his wife fell down the stairs and fractured her leg To bring home the three ill children and the wife with a fractured leg was a matter of some concern This was safely accomplished, and four days later he had a severe bleeding

In these examples hæmorrhage followed upon periods of stress In two of the four patients gastrectomy had already been performed, but in spite of this protection, faced as they were with events in their lives which caused tension, hæmorrhage followed It is to be noted that the interval between the event and the bleeding was not more than a few days Stories of increased responsibility were given by 16 out of the 50 and in this series 10 out of the 16 were under 50 years of age

ILLNESS AND TROUBLE IN THE FAMILY

CASE 10.—A man, aged 46, married twice, four children, 19–24, is "of a worrying nature" and sleeps so heavily that it "would need a brass band" to waken him He is "extremely active" and says "The only thing that makes life bearable here in hospital is getting up I can't read—must be doing something" He is "very methodical and thorough" and, although he is very irritable, he "doesn't show it outwardly" In 1918 he ran into the traction-pole of a pair-horse van and, although he had no immediate symptoms, he "always anticipated trouble from that blow in later years" "I felt it strike my backbone" There were "no symptoms at all till Dec 31, 1937," when he developed "a dull uncomfortable pain" in the upper abdomen It was not enough to put him off his food and, on coming home on Jan 2, he said, "No pain to day" and had his usual supper The next morning is a little hazy in his memory, but his wife found him "standing, dazed, in the lavatory, clawing the walls saying 'I can't get out'" She led him back to bed, and he fell asleep Two hours later he got up and vomited a large quantity of blood

The wife seemed to have been a little unconcerned, and inquiry disclosed important facts Although he had previously said that he had never had a day's illness before the hæmatemesis, after the death (1922) of his first wife, for whom he had a strong affection, he was extremely upset and described himself as "nearly cracked for two years I used to do my driving with tears streaming down my face It affected my stomach, I remember that I put the four children (then aged 3 to 8) in a home at 12s a week each and went without my dinner two days a week to pay for it What upset me was that neither father nor mother nor my sister offered to help in any way" "Home wasn't happy—father was pensioned off by the brewery because he was always drunk Mother was my God until my wife died, and she wouldn't help me If I would go and have a drink with my parents they would see me, but I'm T T I did the 100 yards in 11⅕ last year" (he is 46) "Mother's health is going since October Everything seems to be blowing up at once" "My second wife is a lot of worry The children will all be going very soon—they've all got engaged in the last two years—then I'm going into a single room and she can come or go as she likes To make things worse, promotion is due any day"

CASE 11.—A man, aged 50, consulted one of us in 1934, with signs and symptoms of a duodenal ulcer Progress was uneventful, and he enjoyed good health for four years While returning home from business one evening his car skidded and he and his three companions were badly injured All were admitted to the nearest hospital, where it was found that he had sustained a fractured femur Extension was applied, and his convalescence appeared to be smooth At this time he complained of no dyspepsia The period of extension over, he was instructed to move and exercise his leg, under the guidance of the house-surgeon, when, to his dismay, the callus gave way and his leg fell helpless on the bed This caused bitter disappointment Extension was reapplied for another six weeks His wife saw him on the day of the disturbing event, and he expressed the opinion that he was "done for" The leg would not mend, he would be unable to walk, and he would not be able, as was essential, to get about to obtain business The world, so far as he was concerned, was finished, for his business was a one man show, held together by his wife during his incapacity Next day he complained of flatulence, and four days later the surgeon's attention was called to the pulse-rate of 120 and the pallor of the patient That day his stool was black and he vomited blood

It is of interest to note that not only had this man enjoyed four years' freedom but that after the accident no symptoms of dyspepsia appeared while his leg was in extension the first time He knew that within six to eight weeks he would be well and fit for work again But the failure of sound healing meant to him the end of his ability to work and, therefore, financial ruin Four days after this mental turmoil hæmorrhage took place

Fifteen such examples of trouble or illness either of the patient or of his family, were observed by us in this series, preceding the hæmorrhage

CASES WITHOUT EXTERNAL EVENTS

In 11 patients our inquiry discovered no precipitating event which could be regarded as of importance in producing an emotional disturbance before the hæmorrhage, but we feel that one of the histories is worth recording to demonstrate the predisposing characteristics

CASE 12.—A married woman aged 39, with children of 14, 12, and 10 She was the youngest of nine children and is "afraid she got spoilt" She was "nervous of everything" till she was 10 and remembers having "wind" even then She improved later and became the sole support of her parents until they died, just before her marriage at 25 Four years ago she began to go out as a daily maid to ease the financial strain of three growing children In 1936 she was "run down" and had menorrhagia She has found her work exhausting in the past year (1937) and is "getting nervous again like when I was small I've not been myself since January—I was laid up for three weeks then with a bad cough" She wakes up with a jump very often and is not getting enough sleep "since the summer" Always an active tidy woman, "like mother," she "finds books bore her" She "wants to be doing something but hasn't had the strength in the past year" In December, 1937, she began to have epigastric pains and "went off her food" This made her feel "even less fit for work" She found it particularly trying to hurry home to make the children's midday meal and then back to work and then home to do her own work and make the evening meal She has been on a very light diet since Christmas," and on her 39th birthday she had a hæmatemesis "After I'd brought it up I felt better than I had done for months"

This "negative history" is from the group of 11 in whom we could find no precipitating event preceding the hæmorrhage The histories, however indicate common characteristics which antedated dyspepsia and hæmorrhage in 10 of these patients In other words, 10 out of the 11 showed symptoms of some increase of long standing emotional stress in the period preceding the hæmorrhage

Table I shows the results obtained in the 50 persons observed.

TABLE I—58 HÆMATEMESES IN 50 PATIENTS

Age-group	Events related to—				No events			Total
	Work	Money	Illness	Other	Precedent emotional stress		Total of last two columns "No events"	
					Present	Absent		
20–29	3	1	0	0	0	0	0	4
30–39	5	4	4	0	2	1	3	16
40–49	2	1	1	2	5	0	5	11
50–59	6	7	5	3	3	0	3	24
60–69	0	3	0	0	0	0	0	3
	16	16	10	5	10	1	11	58

Perforation

Employing identical methods we found much the same personality types and precipitating situations in 25 patients with perforated peptic ulcers. In 16 out of the 25 there had been an outstanding event in the patient's life which we felt could be regarded as capable of producing acute emotional stress In the remainder there was little doubt that, although no "acute" events could be found, symptoms of emotional stress, long antedating dyspepsia, were present

CASE 13.—A housewife, aged 30, outwardly calm and balanced, who describes herself as "always worrying inwardly and much more in the last year." She "can't sit still and can't bear to have anything not spotlessly clean." She is "rather sensitive about friends" She had never had any indigestion until the day after the funeral of her husband, who died from silicosis and tuberculosis. On the second day after the funeral she perforated.

CASE 14.—A railway worker, aged 49, with one girl, aged 12 His father and mother were "always out in pubs," and a sister and he ran the home together. In 1923 he began main-line firing on the railway and often would be eleven hours without a meal, with only the company's lodging house at the other end. Since 1936 his wife has been changing and now seems to be both menopausal and paranoid. "As soon as I came home I would see in her eye that her mind had gone. Then she was taken away (to a mental hospital)." "She came home a week before I had this perforation"

TABLE II—SUMMARY OF EVENTS PRECEDING PERFORATION IN 25 PATIENTS

Events related to—					No events		
					Precedent increase in symptoms of emotional stress		
Work	Money	Illness	Other	Total	Present	Absent	Total
2	5	5	4	16	9	0	9

As in the hæmatemesis group, we found the majority, 16 out of 25, showed some acute episode in their lives which preceded the perforation by a few days. In 9, however, although no such events were found, symptoms of long-standing emotional stress were observable Table II records our findings

Discussion

There must be several factors which determine whether an ulcer bleeds or perforates or does neither. The proximity of a vessel of some size, the frequency with which the eroding juice is buffered with food, sudden increase of intra-abdominal pressure by a large meal or a sudden bending of the body, for instance, might easily determine the onset of one of these complications There is, however, one point of common agreement: an ulcer that bleeds or perforates is *active* and erosion is gaining over repair, whether the ulcer concerned is no more than a mucosal erosion or a large indolent crater If the nervous system does play an important part in the ætiology of peptic ulcer, we should therefore obtain some supporting evidence in these two conditions of active ulceration It was for this reason we pursued our inquiry, and our results appear to provide the evidence

Patients often remark on their improvement after one of these catastrophes. Why should an ulcer which has perforated and has only been quickly sutured (often only with a flap of omentum loosely applied) cause so little subsequent anxiety? We cannot recall a single instance of a perforated ulcer in which the patient complained during his convalescence of symptoms indicating renewed activity of the ulcer. Why should a hæmatemesis so often end symptoms? In the latter condition radiography at the end of three weeks often fails to demonstrate an ulcer crater. The evidence points to a rapid healing following these major complications of ulcer. Does this fit in with the nervous origin of ulcer? As we show in our examples, these patients are harassed and worried by their responsibilities and by environmental changes When there is acute uncertainty whether they can get through a situation or not, to give in, to resign and admit defeat is incompatible with their make-up. But when blood is vomited there is a sudden change in affairs and an immediate alteration in their attitude to their difficulties. Their threatened failures are expiated Urgent treatment is called for and all other events become relatively unimportant. Wounded in the battle of life, there is an armistice and with it the possibility of a new orientation. The cares and worries of yesterday now seem relatively unimportant. It may be that this attitude of mind, this new outlook, does play some part in the good results which follow such urgent complications

The "acute" precipitating situations or events which we found to precede hæmorrhage or perforation were identical with those we already found to operate in the dyspepsia of uncomplicated ulcer. The time-interval was found to be a matter of days Tension produced by uncertainty in work and relating to money matters commonly dominates the picture, but illness of a member of the family or of the patient himself played a part in some instances The story of the sea captain illustrates the type of tension—the uncertainty in his mind, over a few days, whether he could land his cargo safely in port The nurse we quoted is a similar example—suddenly placed in what was to her a responsible job, there followed acute tension and the subsequent hæmorrhage Our figures are sufficient, we think, to implicate emotional stress and the nervous system in these two complications and, therefore, in the ætiology of peptic ulcer—for of 58 hæmatemeses 47 were associated with preceding acute tension, as were 16 of 25 perforated ulcers

If we are to accept the view of the ætiology of peptic ulcer implicit in these findings, there are corollaries in *designing* treatment Our practical therapy should include an attempt at prevention of these complications. In known ulcer patients avoidance of increased responsibility or of sudden changes

in responsibility and encouragement of a more even life with an abundance of time to execute each task may help in the right direction and during unavoidable stress and anxiety the frequent buffering of hyperacidity is rational But in our medical attempts at prevention by far the most important point, we consider, is to facilitate the conviction of the patient that his mind is capable of bringing distress to his stomach To the lay person the mind is often something encased in the head, far removed from the stomach That the one can influence the other is, to him, not always sound medicine, and it is surprising how reluctant some remain, in spite of repeated recurrences, to be convinced that there is an association Once, however, the patient accepts this relation, he can, we think, do much to put his house in order

Summary

(1) Events capable of producing unusual emotional tension were found to precede hæmatemesis and perforation in 63 out of 75 patients

(2) These events preceded the hæmorrhage or perforation by a few days and usually related to increase of responsibility, financial difficulty, and illness or trouble in the family

(3) The bearing of this evidence on the etiology of ulcer and on the treatment of the ulcer patient is briefly discussed

Thanks are due to the generous anonymous benefactors of the Tavistock Clinic, whose support made this investigation possible for one of us (A. T. M. W.), to Sir Frederick Menzies for access to cases at Lambeth Hospital, to the medical staff at Central and North Middlesex Hospitals for similar privileges, to members of the staffs of Hounslow and Wood Green Hospitals for their kind co6peration, and to our colleagues at the Royal Free Hospital and the Hospital of St John and St Elizabeth

HÆMORRHAGE IN PEPTIC ULCER

A REVIEW OF 241 CONSECUTIVE CASES

BY J. GIBSON GRAHAM, M.D. Glasg., F.R.F.P.S.
CLINICAL TUTOR AND LATE DISPENSARY PHYSICIAN, THE WESTERN INFIRMARY, GLASGOW

J. C. ALEXANDER, M.B. Glasg., F.R.F.P.S.

J. D. OLAV KERR, M.B. Glasg.
CLINICAL TUTOR AND EXTRA DISPENSARY PHYSICIAN TO THE INFIRMARY

THE orthodox management of hæmorrhage in peptic ulcer has recently been subjected to criticism, and dietetic methods of treatment have taken on a new interest in view of the admirable results obtained by Meulengracht (1935) and Witts (1937). Earlier and more liberal mouth feeding has been claimed to have many advantages over the older methods which often amounted to semi-starvation.

Hæmorrhage, the commonest complication of peptic ulcer, was present in 55.5 per cent. of the 434 hospital cases from which the material for this investigation was obtained. However, this proportion of bleeding is probably higher than that actually obtaining, for patients with peptic ulcers often do not seek hospital treatment until some complication asserts itself. Hurst and Ryle (1937) found that bleeding was present in 31.3 per cent. of a series of 1340 private cases of peptic ulcer, and this figure probably represents more correctly the incidence of hæmorrhage in peptic ulcer.

SELECTION AND ANALYSIS OF CASES

In view of the claims made for the new methods of treatment, it was decided to review all cases of peptic ulcer with hæmorrhage in a medical unit of the Western Infirmary of Glasgow, to ascertain the results obtained over a period of ten years (1929–38). During this period the unit treated 4818 patients, of whom 434 had peptic ulcers. Of the ulcer cases 241 (approximately 5 per cent. of the total admissions) had hæmatemesis or melæna or both (melæna being understood to mean the passage of tarry stools). Only cases showing definite clinical evidence of bleeding were included. No case was included in which the bleeding was due to malignant disease, hepatic cirrhosis, hæmopoietic disorder, gastrostaxis or poisoning. Of the 241 patients 145 had hæmatemesis, 60 melæna, and 36 both hæmatemesis and melæna.

TABLE I.—INCIDENCE OF HÆMORRHAGE IN PEPTIC ULCER

Main type of bleeding	Gastric ulcer	Duodenal ulcer	Gastrojejunal ulcer	Site not determined	Total cases
Hæmatemesis	35	69	3	38	145
Melæna	13	42	2	3	60
Hæmatemesis and melæna	11	23	2	0	36
Total	59	134	7	41	241

Table I shows how the cases were divided into four groups: 59 with gastric ulcers, 134 with duodenal ulcers, 7 with gastrojejunal ulcers, and 41 in which the precise situation of the ulcer could not be accurately determined by radiographic, operation, or autopsy findings. The case history has not been considered a sufficiently accurate guide to the type of ulcer present. Witts (1937) has shown how the provisional and proved diagnoses often differ. The group of undetermined site (17 per cent. of the total cases) supports the studies of Hellier (1934), who included in his series of 303 cases of hæmatemesis 72 of doubtful origin and 106 in which the history strongly suggested peptic ulcer but a radiogram was either negative or not obtained. Cullinan and Price (1932) found it possible to determine the exact site of the ulcer responsible for the bleeding in only 44 of 107 patients treated in St. Bartholomew's Hospital. Hurst and Stewart (1929) and Hurst and Ryle (1937) have pointed out that it is common to find no abnormality if radiography is postponed until three or four weeks after gastric hæmorrhage. They say that hæmorrhage appears to hasten healing of the ulcer.

In reviewing the factors concerned in the production of hæmorrhage in peptic ulcer, sex, age, and occupation have to be taken into account. With regard to the sex incidence, males accounted for 60 per cent. of the gastric group and 72 per cent. of the larger duodenal group. The incidence of gastrojejunal ulcer was entirely male. On the other hand, in the group of cases in which the site of the ulcer was in doubt, the incidence was almost equal (20 males and 21 females). It was noted in the gastric group that, whereas the males showed no significant variation due to age, most of the females were between 40 and 60, contrary to the old-established view that hæmat-

emesis was specially common in younger women These results are supported by the findings of Cullinan and Price (1932), who suggest that this may be related to the disappearance of chlorotic anæmia. In the duodenal group the maximal incidence for females was between 25 and 50, the males again showing no significant variation. In considering occupation it must be recalled that the more highly paid sedentary and professional workers were excluded, for the series consisted entirely of hospital patients Thus, in the male group only 11·5 per cent. were in sedentary employment—e g , clerks—whereas 37 per cent. were engaged in heavy manual work As might be expected, most (78 per cent.) of the females were employed in household duties.

GASTRIC SECRETION

Fractional test-meals were given to 191 of the patients investigated Hyperchlorhydria was found in 61 per cent.; 24 per cent were within normal limits on charts prepared after the standards of Bennett and Ryle (1921); 12 per cent had hypochlorhydria; and 3 per cent had complete achlorhydria These last figures are of special interest in view of the finding of Hurst (1935) that excessive secretion of mucus from a concomitant gastritis will reduce the acid level even in peptic ulcer. It is perhaps significant that, where the test-meal showed hyperchlorhydria and the site of ulceration was definitely established, there were 4 duodenal cases for 1 gastric case Table I shows a preponderance of duodenal over gastric ulcers of 2½ to 1 in contrast to this ratio of 4 to 1.

DIETETIC TREATMENT

During the earlier part of the decade under review the treatment of hæmorrhage followed the classical methods of gastric rest, as described by Willcox (1924) More recently, however, the regime was altered by shortening the semi-starvation period and giving the patient a diet of greater calorie value, of the type suggested by Hurst (1931)

Low-calorie intake.—The aim of this earlier method was to ensure complete rest of the stomach by withholding all mouth-feeding for two to four days after admission. Morphine sulphate gr ¼ was given by injection immediately and thereafter twice daily. Hæmorrhagic shock was combated by the administration of rectal saline with glucose On cessation of frank bleeding, 1 oz drinks of albumin-water were given every hour. On the next day the amount was increased to 2 oz. two-hourly, and a similar quantity of peptonised milk was given every alternate hour Thereafter the quantities were increased daily from an initial intake of 12 calories until on the eighth day of this diet the patient was receiving 1450 calories. At this point light diet was begun.

High-calorie intake.—During the last three years of the period under review the preliminary starvation has been shortened and in some instances omitted. The administration of morphine and rectal salines was found to be beneficial and was continued. Many of the patients received from the day of admission a diet of the type suggested by Hurst (1931) for acute ulcer (stage I) The food value of this recent method of treatment—namely, 2900 calories—shows a very substantial increase over the earlier diet scheme. After a variable period of at least three weeks a further increase in diet was permitted (Hurst's stage II), the caloric intake now being some 3500 calories a day. On discharge from hospital each patient was given a sheet of dietetic instructions

Bland diet.—From the beginning of the series in some cases, mainly of milder severity with melæna, an easily digested low-residue diet, having a calorie value of 2500 approximately, with alkalis and atropine, was given from the day of admission.

Table II shows how the admissions in this series were allocated among the different diet schemes and gives the number of deaths in each group. Of the 3 deaths after treatment with bland diet 2 were post operative and 1 due to repeated severe hæmorrhage five days after admission.

TABLE II—ANALYSIS OF DIETETIC TREATMENTS AND DEATHS

Dietetic treatment	Cases	Deaths
Low-calorie intake	165	20
High-calorie intake	44	0
Bland diet used for slight cases	53	3

Of the 241 patients in this series 20 were admitted with hæmorrhage on more than one occasion, making 262 admissions in all

EARLY SURGICAL TREATMENT

Surgical aid was sought in 8 cases in which medical treatment during the first two weeks after admission had not arrested repeated severe hæmorrhage one patient died before any operation was carried out, in another no lesion was found in the stomach or duodenum, and appendicectomy was performed, the patient making a good recovery, in a third case, a woman aged 45, a chronic lesser-curvature ulcer was invaginated, and subsequent pyloric stenosis led to gastro-enterostomy being performed successfully two years later; and the remaining 5 patients died, giving a recovery-rate of 2 in 7 operations In view of these disappointing results, which are in close accord with the findings of Cullinan and Price (1932) and Hurst and Ryle (1937), we feel that the part played by surgery in the early treatment of hæmorrhage from peptic ulcer is very small (Surgical intervention for perforation or for pyloric stenosis is not within the scope of this paper)

FATALITY-RATE IN HÆMORRHAGE FROM PEPTIC ULCER

Recent writings on hæmorrhage in peptic ulcer have shown considerable variations in mortality Meulengracht (1937), in Copenhagen, has claimed the excellent fatality-rate of 1·3 per cent. in a series of 368 cases treated with his full purée diet, and in a later series (Meulengracht 1939) 10 patients died out of 491. Chiesman (1932) has shown a figure of 25 per cent in 191 cases of gross hæmatemesis and melæna treated in St Thomas's Hospital Paterson (1923–24) expressed a generally held opinion when he stated that of patients who bled severely and were treated medically not more than 1 in 9 would die. The extreme variations in the statistics quoted by different authorities, which have been tabulated by Babey and Hurst (1936), are in part due to the differing standards adopted. Some have lowered the fatality-rate by excluding all deaths not directly due to bleeding from the ulcer, whereas others have raised it by excluding from their series the less severe cases with melæna only. Witts (1937) has pointed out that figures which are extremes from mass statistics have done little to clarify the issues as to treatment

There were 23 deaths in this series of 241 patients, giving a fatality-rate of 9 54 per cent. In arriving at these figures, all deaths have been included Thus, among the 23 fatal cases there are 5 in which death was due to some postoperative complication. surgical shock 3, pneumonia 1, and paralytic ileus 1. There have been included, in the patients treated medically, 3 who died with pneumonia, 1 with cerebral thrombosis, 1 with malignant hypertension, and 1 s

chronic alcoholic All these cases have been incorporated in our total of 23 deaths, because bleeding from peptic ulcer led to their admission to hospital Had these cases been excluded and the fatality-rate expressed in terms of patients actually bleeding to death in medical wards, the figure would have been much lower (4 98 per cent), but it seemed more informative to consider the total fatality rate from all causes, as was done by Cullinan and Price (1932) in their careful review of hæmatemesis

The patients who died included 20 males and 3 females the average age at death being 51, and most of them had had symptoms of long duration Of these patients 11 had gastric ulcers 5 duodenal, and 1 a gastrojejunal ulcer, and in 6 the site of the ulcer was not determined Of cases with operative or autopsy proof, acute ulcers were found in 3 and chronic ulcers in 8 (in one instance both varieties were present) The site of all the fatal chronic ulcers was either on the posterior aspect of the lesser curvature of the stomach close to the pylorus or on the posterior wall of the first part of the duodenum These ulcers were closely related to the gastro-duodenal and right gastric branches of the hepatic artery Apart from three postoperative deaths there had been repeated hæmorrhages in all the fatal cases No patient in this series died from a single hæmorrhage

Duration of bleeding.—Whatever the type of treatment employed, no significant variation in the duration of bleeding after admission to hospital was noticed in either sex In this series the average time taken for the fæces to become negative to tests for occult blood was twelve days Meulengracht (1935) has pointed out that hæmorrhage does not necessarily take place during the whole of this period An intravenous injection of normal saline was given in 5 cases and in 14 the severity of the bleeding necessitated blood transfusion

TREATMENT OF THE ANÆMIA

In this paper no attempt has been made to compare the value of the different preparations of iron on any accurate basis The anæmia which results from hæmorrhage in peptic ulcer does not lend itself well to such a study Thus the remarkable powers of recuperation shown by a healthy hæmopoietic system after a single hæmorrhage are well demonstrated by the case of a young adult whose hæmoglobin percentage after hæmatemesis was 43 and rose to 73 in thirty-five days without any iron medication Various preparations of iron were used during the ten year period under observation Of these injectio ferri (Moltens) which was used to some extent in the earlier years, was found to be of negligible value For example a patient was given thirty two daily injections with an increase in hæmoglobin of only 7 per cent Other preparations used were iron and ammonium citrate and the saccharated carbonate of iron. These both gave excellent results, as the following typical cases show —

(1) A man received gr 90 of the scale preparation daily for twenty-two days his hæmoglobin rising from 37 to 68 per cent

(2) With gr 90 of the saccharated carbonate of iron daily a rise of 15 in the hæmoglobin percentage took place over a period of thirty five days

CONCLUSIONS

In the present series in which deaths from all causes have been considered the fatality rate is 9 54 per cent Three types of treatment have been employed during the decade under observation The fatality-rate in the 165 cases treated with the original low calorie intake diet was 12 1 per cent Throughout the ten year period under review patients with massive hæmorrhage were usually treated by this method The 53 cases treated with bland diet had a fatality rate of 5 6 per cent There were no deaths in the 44 cases treated with the recent high calorie intake In an endeavour to assess the value of this more liberal diet, the fatality rates in all types of cases have been contrasted before and after the beginning of its use A reduction from 10 8 to 6 15 per cent followed its introduction, the former figure being the fatality rate in 169 patients during the first seven years of the period under review It seems reasonable to conclude that more generous feeding is an important factor in assisting recovery from hæmorrhage in peptic ulcer

The extremely low recovery rate after operations—2 in 7 in this series—indicates the extremely hazardous nature of surgical intervention in recent hæmorrhage in peptic ulcer Moreover, as happened in one of our surviving cases, no definite bleeding point may be found at laparotomy Consequently, the function of surgery in hæmorrhage from peptic ulcer appears to be very limited

SUMMARY

(1) A series of 241 consecutive cases of hæmorrhage in peptic ulcer has been reviewed, mainly from a therapeutic aspect The patients were divided into four groups 59 with gastric ulcers, 131 with duodenal ulcers, 7 with gastrojejunal ulcers and 41 in whom the precise situation of the ulcer could not be accurately determined Males accounted for 60 per cent of the gastric ulcer group and 72 per cent of the larger duodenal group

(2) Hyperchlorhydria was present in most (61 per cent) of the patients, but 12 per cent had hypochlorhydria and 3 per cent complete achlorhydria

(3) Recovery rates after operation have shown that the part played by surgery in the treatment of hæmorrhage in peptic ulcer is very small

(4) In this series the fatality-rate from all causes was 9 54 per cent In the earlier part of the period under investigation when the treatment given was the classical low calorie intake, the fatality-rate was 10 8 per cent in 169 patients, but after the introduction of more generous diets the figure fell to 6 15 per cent in 72 patients None of those treated with the newer high-calorie intake (Hurst's diet schemes) died

(5) The majority of the fatal cases had chronic ulcers in the pyloric region, either on the posterior wall of the stomach (11) or of the duodenum (5) vessels having been eroded All the patients that died had had hæmorrhage more than once

(6) In the treatment of the consequent anæmia excellent results followed the administration of iron and ammonium citrate, or the saccharated carbonate of iron, in large doses, but remarkable recuperation of blood may follow a single hæmorrhage, without any iron being given Injections of iron were almost useless

Our sincere thanks are due to Dr George A Allan, who suggested this investigation, placed his case records at our disposal, and greatly helped us with advice and criticism, and to Miss F Rose, sister-dietitian in the Western Infirmary, for her valued supervision of the diet schemes

LATE SEQUELÆ OF PULMONARY EMBOLISM

BY THOMAS H. BELT, B Sc., M.B. Toronto

SENIOR ASSISTANT IN PATHOLOGY, BRITISH POSTGRADUATE MEDICAL SCHOOL, LONDON

FROM a clinical point of view pulmonary embolism is rarely if ever regarded as the cause of chronic disease The usual picture is that of a more or less acute illness which passes fairly quickly from one episode to another and ends in either death or recovery in a matter of days or weeks. Yet a careful study of the pulmonary arteries at many autopsies makes it clear that we have sometimes to reckon with long-standing lesions and morbid processes which appear to be the result of emboli lodged in the lungs months or even years before death

For want of a better term the condition which I propose to describe may be called "chronic embolisation of the pulmonary arteries" I have collected four representative cases which illustrate the progressive phases of this morbid process The first patient survived for three or four months and the others for longer periods up to six years or more. The nature of the lesions became apparent only at autopsy Then it seemed evident that what were probably embolic seizures had been regarded clinically as heart attacks or, if the lung was infarcted, as pneumonia The diagnosis was rendered the more difficult during life by the lack of any manifest source of emboli My colleague Dr Paul Wood has now had some success in recognising this type of case clinically and will shortly report his findings. Only a brief outline of the clinical histories is given here My main object is to describe certain unusual lesions of the pulmonary arteries and to show that they are of embolic origin.

CASE-RECORDS

CASE 1.—A tall robust young man, aged 28, previously healthy, injured his left knee in a motor accident The wound became infected, and the thigh had to be incised for the drainage of pus, but after five weeks recovery seemed more or less complete. Thereafter he suffered recurrent attacks of pulmonary embolism with pleuritic pain and bloodstained sputum. There were three or four episodes of increasing severity at intervals of some weeks before the fatal seizure five months after the injury.

Autopsy.—Much dilatation and some hypertrophy of the right ventricle Evidence of congestive heart-failure. Large emboli, old and recent, of pulmonary arteries (fig 1). Old and recent thrombosis of left iliac veins. No septic focus found in relation to the thrombosed veins.

Earlier post-mortem investigations on pulmonary embolism have made it abundantly clear that migration of venous thrombus to the lungs is seldom confined to a single event but tends to recur (Belt 1934) In most instances there are multiple emboli, and it is usually obvious that they have migrated at intervals rather than all at once. Case 1 is an example of recurrences over a period of three or four months. The emboli apparently arose from a long-standing subclinical thrombosis of the left internal and common iliac veins This thrombosis was probably a sequel to the injury of the left leg, but the causal relationship was no longer apparent. Three of the larger emboli may be seen in fig. 1. They are numbered in the apparent order of their occurrence. The first (1) is a firmly adherent tough contracted mass of organising clot which practically occludes the right lower branch It is partly recanalised and would correspond to one of the earlier seizures, probably three months before death The second (2), which is firmly adherent to the vessel wall and partly bleached though not yet contracted,

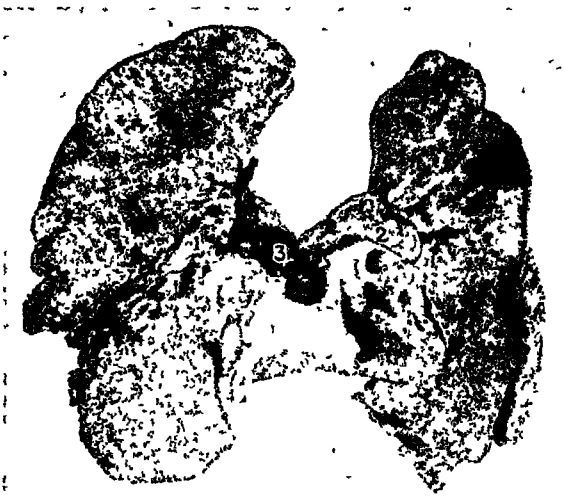

FIG 1—Lungs and main pulmonary arteries of case 1, showing three large emboli numbered in the order of their occurrence · (1) probably two or three months old and so far organised as to be tough and contracted, (2) firmly adherent, partly organised, probably six weeks old; and (3) recent (Pathological museum, British Postgraduate Medical School)

might be six weeks old The third embolus (3) caused death within a few minutes. The degree of obstruction occasioned by these emboli had had an obvious effect on the right ventricle. It was not only dilated but also hypertrophied, and the abdominal viscera showed chronic vascular congestion. Had this patient escaped the final embolism he might well have developed the same sort of picture as that of case 4.

CASE 2.—Female, aged 77, died on April 4, 1933. An anæmic old lady with effort dyspnœa and periodic swelling of feet for two years Recurrent attacks of pleural pain and weakness for about six months In hospital from Nov. 1 to Dec 20, 1932, treated for coronary disease of heart complicated by bronchopneumonia Readmitted on Feb 25, 1933, with air-hunger, having suffered two sudden painless attacks of faintness and suffocation a short time previously. Gradual decline with congestive heart-failure

Autopsy.—Heart weighed 300 g The pericardium was adherent, the right heart much dilated Secondary branches of pulmonary arteries practically all occluded with old and recent emboli (fig. 2) which had arisen from a silent thrombus in right external iliac vein. Several small hæmorrhagic infarcts of the lungs with associated pleurisy.

Here there were too many complications to afford a good general picture of the late results of embolism, but the case is noteworthy for certain morbid ana-

tomical features which make it possible to trace the fate of an embolus through various stages of organisation to its ultimate cicatricial state The structure marked (1) in fig 2 would scarcely be recognised as an embolus except in the company of the later arrivals, for it has been transformed into a tough white cord like structure It has a three-cornered attachment, its ends are secured to the wall of the larger vessel, and its middle to the promontory of an intervening bifurcation Its length lies more or less parallel to the direction of the main blood stream Microscopically it has the character of a fully organised blood clot The surface is covered by an indistinct endothelial membrane and slightly roughened by a few minute deposits of platelet thrombus Here and there throughout the mass are clusters of hæmosiderin pigment, a point of some importance to be discussed more fully in the account of the next case

CASE 3.—A stout blind man, aged 48, who died on Feb 5, 1939, with heart failure a few days after surgical repair of a congenital diaphragmatic hernia Little is known of his previous history except that he had had effort dyspnœa for some months

Autopsy.—Postoperative paralytic ileus Cor pulmonale with chronic vascular congestion of viscera Fibrous stenosis of pulmonary arteries, possibly due to organised emboli (figs 3 and 4) Left femoral and popliteal veins scarred and trabeculated like the vein in fig 7 No recent emboli were found

At first sight the peculiar changes in the pulmonary arteries of this case are not easily recognised as of embolic origin Each lesion consists of a fibrous cord like structure attached only at its extremities, so that its length is suspended tightly but freely in the lumen of the vessel, more or less parallel to the direction of the main blood current It is similar to the older lesions in the preceding case Under the microscope the appearances are those of an organised clot with rich deposits of hæmosiderin These fibrous bands must be but a fraction of the size of the original clot The contraction which they have undergone has puckered the vessel and reduced

FIG 2—Part of right lung of case 2 showing secondary divisions of pulmonary artery with four emboli numbered in the order of their occurrence (1) solid, white, fibrous, probably six months old, (2) partly organised, (3) and (4) recent (Pathological museum, Banting Institute)

the lumina, particularly in the tertiary branches, producing a good deal of obstruction, which had caused a notable hypertrophy of the right heart The primary and secondary divisions of the pulmonary arteries were dilated, rather inelastic, and flecked with fatty streaks, probably as a result of pulmonary hypertension

It might well be asked, Was not the original clot autochthonous rather than embolic? The answer is in the negative for the following reasons: (1) the

FIG 3—Part of right lung of case 3 showing secondary divisions of pulmonary artery with one large fibrous cord (stretched over forceps) representing a completely organised blood-clot

FIG 4—Part of left lung of case 3, showing secondary divisions of pulmonary arteries with numerous trabeculæ representing organised clots Many are deeply coloured with old blood pigment Tertiary divisions scarred and stenosed

FIG 5—Part of left lung of case 4 showing pulmonary artery to lower lobe (hilus held open with match A) with puckered trabeculated scar apparently representing result of embolism six years earlier

lesion conforms to the pattern of an old embolus as seen in the previous case; (2) it is attached only at its ends to the arterial wall, whereas an autochthonous thrombus might be expected to be more sessile, (3) the location of the lesion corresponds to that where emboli commonly lodge; (4) the slender elongated form suggests that the original clot was cylindrical like an embolus; (5) its orientation suggests that it was originally a loose-lying clot whipped out in the direction of the blood-stream; (6) there is no obvious intrinsic cause for thrombosis in these vessels; (7) similar organised clot was found in the leg veins, providing proof of a potential source of embolism; and (8) there is strong evidence to show that embolism is many times commoner than autochthonous thrombosis of the pulmonary arteries (Belt 1939b)

The lesion which we regard as an organised embolus is not necessarily static. There may be microscopic deposits of secondary thrombus on its surfaces These tend to recur and undergo organisation somewhat like the verrucose vegetations of rheumatic heart-disease and may lead to progressive scarring; or there may be extensive development of secondary thrombus, as in case 4.

CASE 4.—A stout plethoric female, aged 67, chronic alcoholic, with congestive heart-failure, died unexpectedly on Dec 11, 1934, shortly after a sudden painless seizure of breathlessness. Six years earlier she had had a similar seizure, which was diagnosed as a heart attack and followed by an illness regarded as pneumonia. Since then she had been weak, short of breath, cyanosed, and subject to swelling of the feet and ankles

Autopsy.—Cor pulmonale, old scarring of pulmonary arteries (fig. 5), recent emboli of tertiary branches, and a large plaque-like thrombus of right main branch (fig. 6) The emboli had arisen from leg veins, which showed old and recent thrombosis (fig 7). The lungs were not infarcted

FIG. 7—Right femoral vein of case 4, showing cicatricial trabeculation, thickening, and distortion due to organised thrombus Recent thrombus in lower part had given rise to fresh emboli.

This is the type of case which best exemplifies the late sequelæ of pulmonary embolism. The clinical picture was not unlike that of Ayerza's syndrome. The right ventricle was as large and almost as thick-walled as the left (fig 6), affording a good example of cor pulmonale There was extensive scarring of the larger pulmonary vessels, which probably dated back six years to the serious illness recorded in the history Here the scar consists of a tangled contracted network of fibrous trabeculæ (fig 5)

Again it may well be asked, Why is this lesion to be regarded as embolic? The answer is, For the same reasons as advanced in the preceding case Here there is even less doubt, for the fatal issue was determined by embolism

The large plaque-like thrombus half filling the right pulmonary artery (fig. 6) is of some duration and has its roots in an old scar similar to the scar on the left side pictured in fig 5 It is not difficult to see how such scars as these might result from the organisation of large emboli like those in case 1, the location is more or less the same in both cases —namely, just inside the hilus

FIG 6—Heart and lungs of case 4, showing large tongue-shaped thrombus half filling right pulmonary artery; dilatation of pulmonary trunk, and hypertrophy of right ventricle. (Pathological museum, Banting Institute.)

DISCUSSION

Cord-like scars in the pulmonary arteries similar to those described have been observed in a few instances by others Zahn (1889) recorded one case with a peculiar web-like fibrous lesion which he regarded as a congenital anomaly Saphir (1932) saw the condition twice and took it as evidence of organised thrombus He thought the thrombus had been autochthonous, due to atheromatous change, though he said he could not be sure that it was not embolic It is perhaps significant that Zahn's patient and one of Saphir's died of pulmonary embolism.

Like Møller (1922), who observed the lesion in 4 cases, I have little doubt that it represents a late result of embolism In routine autopsies one sees so many emboli of the lungs (Belt 1939a), if one is on the look-out for them (emboli which, for the most part, are undiagnosed clinically), and so few cases of primary pulmonary thrombosis that, when it comes to a question of deciding between the two, I always think of embolism first, though I am well aware that this is not the common teaching Of my 4 cases probably no one will doubt that the first 2 are examples of recurrent embolism. Concerning the others there may be some question, but I have tried to show how the emboli in the first 2 may have their counterpart in the older lesions of the second 2, and I have proved a potential source of embolism in all.

Case 4 might well have been regarded as an instance of primary pulmonary thrombosis, if a careful dissection of the pulmonary arteries and peripheral veins had not been made The recent emboli and the long-standing venous thrombosis might easily have been overlooked. Of all the cases of pulmonary thrombosis collected by Fowler (1934) one may wonder what proportion of them would have shown evidence of an embolic origin if it had been sought.

Among the few people to suggest an embolic background in cases of this type are Møller (1922) and Ljungdahl (1928)

If our interpretation be correct recurrent embolism is a possible cause of chronic pulmonary obstruction and cor pulmonale Some cases of Ayerza's disease may perhaps also be explained on this basis It seems to me that stenosing lesions of the pulmonary arterioles, usually regarded as a form of endarteritis obliterans, may sometimes be caused by minute embolisms recurring perhaps over long intervals, but I put this observation merely in the form of a suggestion

SUMMARY

After a non fatal attack of pulmonary embolism recovery is not always complete Not only does the embolism tend to recur but also organising emboli may produce cicatricial stenosis of the pulmonary arteries and lead to secondary thrombosis

Four cases are described which purport to show how these sequelæ of pulmonary embolism may sometimes cause a chronic illness by producing progressive pulmonary obstruction

Recurrent thrombo embolism may arise more or less de novo without antecedent illness and without obvious thrombophlebitis

I am indebted to Prof Duncan Graham, of Toronto and Sir Frederick Menzies, chief medical officer of health for the county of London, for permission to publish these case-records, and to Mr E V Willmott and Miss M H Shaw for the care they have taken with the photographs

DURATION OF LABOUR IN PRIMIPARÆ

By VIOLET SPILLER, M D Geneva M R C S, D P H

LATE INPATIENT OBSTETRIC ASSISTANT TO THE OBSTETRICAL AND GYNÆCOLOGICAL UNIT, ROYAL FREE HOSPITAL LONDON

THE effect of various factors on the duration of labour is one of the questions uppermost in the mind of anyone controlling the administration of analgesics and anæsthetics in labour The many inquiries that have been made are for the most part incomplete and not comparable, the probable error of the mean not having been calculated

An analysis has here been prepared of the duration of the first and second stages of labour in 1400 consecutive primiparæ delivered by the vaginal route (including forceps cases) in the obstetrical and gynæcological unit of the Royal Free Hospital from January, 1935, to December, 1937 The ages of the patients range from sixteen to forty five years, and, as can be seen in table I nearly two fifths were between twenty four and twenty seven Only 3 5 per cent were under twenty, and 6 5 per cent were over thirty three For the present purpose those between eighteen and thirty nine have been divided into two year age groups

In fig 1 the average lengths of the first and second stages taken together and of the second stage alone are shown graphically The graph seems to support the popular belief that the younger the mother the shorter the labour, thus agreeing with De Lee (1933) Nathanson (1935), Duchman (1932), Miller (1931–32), and others When, however, the differences between the means (see table II) and the standard errors of the differences between the means for the duration of labour for each age group are estimated, it is found

TABLE I—DISTRIBUTION OF CASES ACCORDING TO AGE

Age last birthday	Number of cases			Total	Per cent

that the difference in duration from one age-group to the next is not statistically significant But if the duration in one age-group is compared with that in a group separated from it by several years the difference becomes slightly significant

The correlation between age and duration of labour is low but definitely positive ($r = +0.12 \pm 0.02$) This fits in with the experience of Berkeley and Bonney, though they say that the increase is only slight after the age of thirty. Frey (1933), Frey and Maeder (1933), Quigley (1931), and Calkins, Irvine, and Horsley (1930) do not admit that age has any influence on the course of the first and second stages Calkins, however, was investigating a group consisting of multiparæ as well as primiparæ, whereas we are there dealing with primiparæ only. Also their series was even smaller than ours (1250) They found no evidence of correlation between age and length of labour, and conclude that the only important factor is parity.

All the patients in our series received analgesics, such as potassium bromide, gr. 30, with chloral hydrate, gr 30, and gas and air by the Minnitt apparatus; a small proportion received drugs of the barbituric acid group, Opoidine or rectal ether, during labour. Many patients were of the highly nervous type

It is thus interesting to compare the average length of labour in this series with that reported by others Quigley (1931) found that the average length of labour in 300 patients of thirty and over was 17 hours. Roeder (1937), who considers patients of thirty-five and over elderly, found that in 113 such cases the average length of labour was as low as 13 hours 9 min. In Nathanson's (1935) series of 186 cases aged between thirty-five and forty-six, the average was 18¾ hours. Daichman (1932) grouped those aged thirty-eight to forty-four as elderly and found that the average in 48 such patients was 22½ hours. Douglas Miller (1931–32) found the average in 88 cases of forty and over was 21½ hours

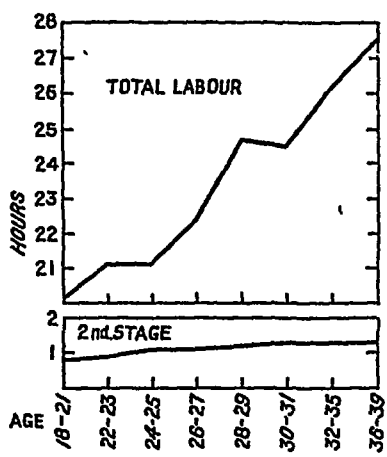

FIG. 1—Average length of total labour (above) and the second stage (below) in age-group.

The average length of labour of all the patients between the age of eighteen and thirty-nine in the present series was higher, being 23 hours 39 min. But if we take, for example, the group of patients aged twenty-four to twenty-seven (nearly two-fifths of the total) we find that 65 per cent. of these had a considerably shorter labour than the average, which for this group was 22 hours, and half the patients had labours lasting between 7 and 18 hours This is illustrated in fig 2, where the peak on the graph, or, statistically speaking, the mode, is at 13 hours.

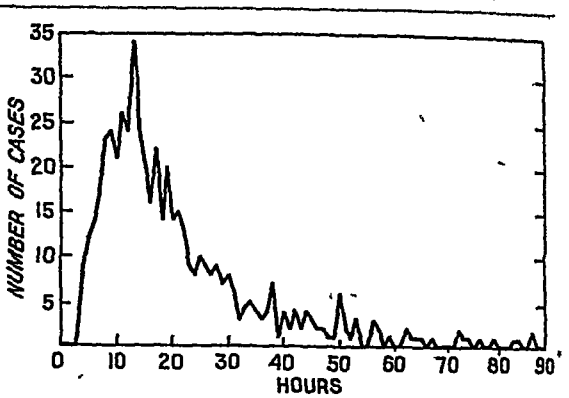

FIG 2—Distribution curve of length of total labour in patients aged 24–27

SUMMARY

In 1400 consecutive primiparæ delivered by the vaginal route, all of whom received analgesics during labour, there was a low but definitely positive correlation between age and duration of labour

The average length of labour of those between the ages of eighteen and thirty-nine was 23 hours 39 min Half the patients had labours lasting less than 20 hours

I am indebted to Prof Amy M. Fleming for her help with this work

BLOOD COMPLEMENT IN ACUTE GLOMERULONEPHRITIS

AND TOXÆMIA OF PREGNANCY

BY SCOTT THOMSON, M.B. Edin, D.P.H.
W. MELVILLE ARNOTT, B Sc, M.D. Edin, F.R C.P.E.
LECTURER IN THERAPEUTICS IN THE UNIVERSITY OF EDINBURGH; AND
G. DOUGLAS MATTHEW, M D Edin, M.R C.O.G.
TUTOR OF CLINICAL GYNÆCOLOGY AT THE ROYAL INFIRMARY, EDINBURGH

MANY claims have been made that blood complement is reduced in amount in several diseases

Paul and Pélyi (1935) described a slight fall in complement in allergic states, but the alteration was not great and was not found by Tilden (1934) More pronounced disturbances of complement activity have been described in yellow fever by da Costa Cruz (1929a and b), and this was not due to anticomplementary activity. Goldner (1929) concluded that complement was reduced in amount in all diseases involving extensive damage to the liver, and slight reductions have been described in eclampsia by Goldschmidt-Fürstner (1931) Slight alterations have been described in acute rheumatism by Veil (1932) and by Veil and Buchholz (1932) and in pneumonia by Dick (1912). In most of the above instances the disturbance was insignificant, and very few investigators made any examination of the range of complement activity in normal people.

A very pronounced disturbance in complement activity is found in acute nephritis (Gunn 1914, Kellet 1936, Kellet and Thomson 1939), and this fact may throw some light on its ætiology. Longcope (1929) and his co-workers have observed that the skin reactivity of patients with glomerulonephritis to filtrates of cultures of hæmolytic streptococci is very much greater than in other forms of streptococcal infection, such as uncomplicated tonsillitis. According to Friedemann and Deicher (1928) the blood of patients with postscarlatinal glomerulonephritis contains a greater concentration of antibodies than does the blood in non-nephritic cases of scarlatina at a comparable stage of convalescence. Further, acute glomerulonephritis has been produced in rabbits by a nephrotoxic serum (Masugi 1933, 1934, Arnott, Kellar, and Matthew 1936). The clinical, bacteriological, and experimental evidence, therefore, appears to indicate that diffuse glomerulonephritis is due either to a greatly exaggerated acquired sensitivity of the kidneys to the products of the streptococcus or to the effects of an exceptionally vigorous antibody-antigen reaction, such as might take place during the period of regression of the infection.

It has been suggested, apparently on comparatively little evidence, that pre-eclamptic toxæmia and eclampsia are also due to a similar type of reaction. Pregnancy toxæmias and acute nephritis have several points in common: both of them are associated with albuminuria, hypertension, and œdema, and both tend to progress towards a hypertensive encephalopathy. There are also glomerular changes in eclampsia which, however, are much less pronounced than in glomerulonephritis (Baird and Dunn 1933, Kellar, Arnott, and Matthew 1937). In the light of these known similarities between acute glomerulonephritis and eclampsia an attempt has been made to determine whether the similarity includes a reduction in blood complement. For this purpose many normal people were examined to establish the normal range of blood complement, which was then examined in cases of acute nephritis, healthy pregnancy, pre-eclamptic toxæmia, and eclampsia.

TECHNIQUE

Various amounts of serum were added to 0·5 c.cm. of a 3 per cent. suspension of sheep's red cells sensitised by the addition of 7 M.H.D. of hæmolytic antibody. The range of serum examined was 0·02, 0·04, 0·06, 0·08, 0·1, 0·15, 0·2, 0·4 c.cm., and the activity was taken to be represented by the reciprocal of the smallest amount of serum producing complete lysis of the cells after incubating the mixtures for two hours at 37° C.

So that the results of all the tests done over a given period should be comparable, a preserved complement was titrated with every batch. According as the activity of the preserved complement varied with the suspension of cells used, adjustments, usually slight, were made in the activities of the complements under test.

RESULTS

The complement content of the blood of 126 normally healthy patients in hospital for some minor gynæcological condition was observed. In this control series complete hæmolysis of the test amount of cells was obtained with 0·2 c.cm. or less of serum in 122 patients, and in the remaining 4 patients 0·4 c.cm. of serum was necessary to produce complete lysis. In these 4 there was obvious partial lysis with 0·2 c.cm. and with 0·1 c.cm., although 0·4 c.cm. was the amount required to produce complete lysis.

Acute nephritis.—Of 18 patients with acute glomerulonephritis 5 had their blood complement estimated once, 3 twice, and the remaining 10 three or more times. Of the 5 patients examined only once 1 showed a normal complement content, and of the 3 examined twice 1 showed a normal complement. In each of the remaining 16 a reduction of complement was found. In many instances there was apparently no complement present at all, but there was no obvious correlation between complement content and any of the clinical features, such as albuminuria, hypertension, and fever. In 2 cases a complete absence of complement activity was found on the same day that the blood-urea was normal, showing that the absence of complement was not due to an inhibition of its activity by retained nitrogenous substances. In another case the blood showed only the slightest trace of complement long after the patient had been discharged as cured.

Pregnancy control series.—Complement estimations were carried out on the blood of 157 women at all stages of pregnancy, and all showed a normal activity.

Pre-eclamptic toxæmia.—In 33 patients with typical pre-eclamptic toxæmia, characterised by hypertension, albuminuria, and œdema, who were examined on one or more occasions, no reduction in the complement was detected.

Eclampsia.—Repeated examinations were made on 8 cases of eclampsia during the convulsive phase, and no disturbance of blood complement was found.

DISCUSSION

We can therefore confirm the almost invariable reduction in complement in the blood in acute glomerulonephritis. There is apparently no alteration in the blood complement in pre-eclamptic toxæmia or in eclampsia. The similarity between acute glomerulonephritis and eclampsia does not, therefore, include this suggestion of a disordered immunity reaction. It appears likely that the similarity is due to the fact that they both share a widespread arteriolar spasm which is productive of hypertension, albuminuria, encephalopathy, and possibly œdema.

SUMMARY

Blood complement is reduced in acute nephritis, but there is no reduction in the toxæmias of pregnancy.

The work was done during the tenure of a Shaw Macfie Lang fellowship (W. M. A.) and a Kirk Duncanson fellowship of the Royal College of Physicians (G. D. M.). We wish to express our indebtedness to the Medical Research Council and the Earl of Moray Endowment for expenses grants. We are much indebted to Prof. D. M. Dunlop, Dr. T. J. Mackie, and Dr. R. W. Johnstone for their advice and encouragement and to the physicians of the Royal Infirmary and the Royal Maternity Hospital for access to patients under their care. We are also grateful to Dr. W. I. C. Morris, consulting obstetrician to Ayr county council, for samples of blood from cases of eclampsia.

HÆMATURIA DURING TREATMENT WITH M. & B. 693

BY T. C. BACKHOUSE, M.B. Melb., D.P.H.

GOVERNMENT PATHOLOGIST AND BACTERIOLOGIST, RABAUL, NEW GUINEA

AT the end of October, 1938, I began to treat native pneumonia cases with M. & B. 693. The ninth patient referred for this treatment was a boy of about 16 who presented signs of acute bronchitis and some suggestion of incipient bronchopneumonia. Although he did not seem to be altogether a suitable case for inclusion in what was supposed to be a trial series, it was decided to treat him.

CASE-RECORD

The boy was given 2 g. of the drug at 2 P.M., 1 g. at 6 P.M., 1 g. at 10 P.M. and no more until the following morning at 6 A.M., when he received another 1 g., making a total of 5 g. in 16 hours. When seen at 8 A.M. he was rolling about and calling out apparently in great pain. He was holding his hands to his suprapubic region and kept trying to pass urine. When he succeeded it was a mere bloodstained trickle, and the act seemed to cause pain. In addition to blood the urine contained an obvious white crystalline deposit, and a white incrustation formed about the urinary meatus. The patient was vomiting at intervals and appeared to have recurrent spasms of pain in the lower abdomen. He did not look toxic or seriously ill apart from his extreme discomfort. The pain was relieved by a small dose of morphia and hot applications, his M. & B. 693 was stopped forthwith and he was put on a potassium citrate mixture and encouraged to drink freely. He continued to pass small amounts of bloodstained urine during that day but the acute symptoms quickly subsided, and by the following morning the urine had increased to a satisfactory quantity and was progressively clearing.

The urine on the day of onset was strongly acid in reaction. Microscopically, the deposit showed masses of red blood-cells and crystals. These crystals, which were to become very familiar objects, resembled in shape the cross section of a fairly thick convex lens with a peripheral portion of one arc shorn off. They occurred singly or in formidable spiky agglomerations. On the second day the urine was light amber, somewhat opalescent, acid, and showed a trace of albumin; microscopically, red cells were still fairly numerous, and there were many crystals of the form described. Next day the findings were similar, except that the lenticular crystals were replaced by an occasional sheaf-like bundle of needle forms. Four days later the urine was relatively normal but still showed an occasional red cell microscopically.

These phenomena were at the time only tentatively ascribed to the effects of M. & B. 693, but the occurrence of similar cases soon put the matter beyond doubt, although it was puzzling that the complication did not seem to have been recorded in the growing literature. But it was not long before records began to appear. Robertson (1939) reports one such case; here crystals were not observed, and if the hæmaturia was accompanied by pain the patient was possibly insensible of it, being a severe meningitis case. Hanssen (1939) reports six pneumonia cases treated with M. & B. 693 with hæmaturia in one; he does not give the microscopic appearances of the urine. Adalja (1939) reports hæmaturia on the fourth day of treatment of a case in Nairobi, but only records red cells in the urinary deposit, again no mention of crystals. More recently Southworth and Cooke (1939) have reported three cases in considerable detail. In one crystals are mentioned as being absent in the urinary sediment, in the second crystals were present but are not described, and in the third there is no mention of crystals. Pain was a prominent symptom in these cases. These writers refer to the experimental work of Antopol and Robinson (1939) which evidently has an important bearing on the problem. They found that rats, rabbits and monkeys fed with sulfapyridine developed uroliths in the urinary tract.

FURTHER CASES

During the eight months October, 1938, to May, 1939, I treated 109 New Guinea natives suffering from pneumonia of various degrees of severity with M. & B. 693, of which 3 died before any significant amount of the drug could have been absorbed. Hæmaturia was encountered 13 times in these cases, and I also met with it in at least 3 other cases with which I was associated. The chief features of the cases are given in the table.

As a rule, about the third or fourth day of medication, but occasionally as late as the sixth day, the patient complains of lumbar, abdominal, suprapubic or penile pain, has some difficulty or pain with micturition and passes scanty urine more or less heavily tinged with blood; at times the specimen gives the impression of being more blood than urine. There is sometimes headache and vomiting a day or so before the onset of hæmaturia, and vomiting is a common accompaniment of the acute stage. In a few cases anuria has persisted for 12 or 14 hours and has caused some anxiety as to the ultimate outcome, but all have cleared up in 24 to 48 hours.

The treatment adopted consisted essentially in withdrawing the drug and getting the patient to take as much fluid as possible. A mixture of potassium citrate with tincture of hyoscyamus was used in most cases. In a few in which anuria threatened to persist a pint or two of hot saline was given into the rectum with apparent benefit. In a few cases 50 c.cm. of 50 per cent. glucose in Ringer's solution given intravenously seemed to have a good diuretic effect.

CRYSTALS IN THE URINE

After the first few cases of hæmaturia the urine of natives under treatment began to be inspected more frequently, and it became apparent that the majority of patients receiving amounts of M. & B. 693 of the order of 5 g. daily, sooner or later develop gross crystalline deposits in the urine. Often the urine is clear when passed but deposits crystals within half an hour. The crystals consist in most cases of the lenticular forms described, but in some instances the deposit has consisted almost entirely of sheaves of fine needles. In 2 cases in which the sheaves were filtered off a second deposit formed and this time was of the lenticular type. Both types of deposit give, after hydrolysis, deazotisation and coupling with dimethylalphanaphthylamine, the colour-reaction by which the presence of the sulph-

SUMMARY OF HÆMATURIA CASES
(All were males)

Serial no. and age	Days of treatment before onset	Total M & B 693 given before onset (grammes)	Chief symptoms and urinary findings
1 (16)	1	3	Suprapubic and penile pain, pain on micturition White incrustation urinary meatus Urine scanty, strongly acid S G 1014, albumin + + fresh red cells lenticular crystals
2 (31)	6	26	Abdominal pain vomiting pain on micturition Urine scanty bloodstained, S G 1018 strongly acid albumin + red cells, lenticular crystals
3 (23)	4	18	Pain on micturition Urine scanty, blood-stained crystalline deposit red cells, lenticular crystals
4 (28)	5	27	Pain in loins and suprapubic region Urine scanty, at *times* 1 *or* 3 c cm, much blood red cells, lenticular crystals
5 (?0)	6	25	Abdominal pain, vomiting Urine scanty to suppressed much blood, heavy deposit of crystals red cells lenticular crystals
6 (26)	5	32	Abdominal pain Urine diminished dark red, alkaline (not fresh) faint spectrum hemoglobin no red cells lozenge crystals and phosphates Very mild transient Further course M & B 693 without recurrence
7 (26)	4	30	Penile and lumbar pain Urine scanty, partial anuria 2 or 3 days red cells lenticular crystals
8 (30)	3	18	Suprapubic pain Urine diminished, altered *blood in first sample later bright* blood strongly acid, red cells lenticular crystals
9 (22)	3	10	Headache, pain lower abdomen vomiting Urine scanty acid S G 1008, red cells, crystals
10 (19)	4	20	No subjective symptoms Urine microscopic blood and sheaves of lenticular crystals
11 (24)	4	20	Severe penile pain vomiting anuria for about 36 hours Urine much blood crystalline deposit
12 (18)	3	12 5	Mild suprapubic pain Urine diminished bloodstained crystals not seen
13 (14)	4	8	No subjective symptoms Urine diminished, blood present albumin + + +, no crystals noted

sulamide drugs is recognised When heated with alcohol and sulphuric acid an odour resembling acetic ether is given off The crystalline substance seems to be an acetylated conjugate of *M & B 693*

The occurrence of such crystals in freshly passed urine containing blood associated with symptoms suggestive of the presence of urinary calculi, inevitably leads to the supposition that the condition is a purely mechanical one caused by the deposition of the crystals in various parts of the urinary tract In this connexion the following case is of some interest, particularly in view of the experimental findings of Antopol and Robinson

An adult male native aged about 30 was admitted to hospital on April 1, 1939 He was said to have suffered from pain in the chest and cough beginning two days previously He did not appear ill His temperature was 99 6° F, pulse-rate 84, respirations 20 per min. Examination of the chest revealed rhonchi scattered over both sides but no localising signs of consolidation He was given no special treatment and remained in statu quo until the evening of the 3rd, when at 6 P M his temperature was 104 1° F, pulse 124 and respirations 48 The chest signs were much the same A blood-culture was taken at 10 P M and next morning showed a heavy growth of type 1 pneumococci Treatment with M & B 693 was then begun and 6 g was given daily for six days (1 g 4 hourly) Owing to vomiting, treatment was interrupted on the 10th, only 1 g being given on that day Dosage was recommenced on the 11th and continued, supplemented by 2 5 g intramuscularly on the 12th and 13th, until the patient died on the morning of the 18th In all, 52 5 g had been given. The blood was cultured daily from the 3rd to the 11th inclusive and was always positive On the 12th meningitis had declared itself by a sudden epileptiform convulsion, and the cerebrospinal fluid was turbid and contained viable type 1 pneumococci

Apart from the signs of purulent meningitis, somewhat congested lungs, and a hypertrophied left ventricle, the interest in the autopsy findings centred about the urinary system The kidneys were swollen and felt tense The right kidney weighed 195 g and the left 205 g On section the cortex of each was swollen and blurred and showed a few hæmorrhagic points The pelvis of both kidneys and both ureters were dilated and contained turbid brownish urine under some pressure Both ureters were dilated to a diameter of about 1 cm and were occluded at their point of entrance to the bladder by a small irregular, gritty and friable concretion about 9 mm by 7 mm The lining of the ureter underlying the concretions was congested and seemed to be slightly eroded There were, however, no signs of recent bleeding and the urine in the bladder showed no blood microscopically The sediment from the fluid in the ureter showed no crystals of the type described in the hæmaturia cases but only some spherical, brownish, radially striated bodies resembling urates The amount of free M & B 693 in the urine was estimated as 85 mg per 100 c cm That in the serum was 9 mg and in the cerebrospinal fluid 6 5 mg The concretion was composed of masses of long narrow rectangular crystals like stacks of sawn timber These were soluble in sodium hydroxide and reprecipitated by hydrochloric acid in somewhat modified and diverse forms, which varied according to the concentration of the solutions used Urate crystals were also present and the murexide test was positive Tests for the sulphanilamide compounds were positive, those after hydrolysis giving about a seven times greater concentration of colour than before Sections of the kidneys showed some desquamation and spoiling of the tubular epithelium, areas of round cell infiltration and scattered hæmorrhages The glomeruli were irregularly distributed and in parts crowded together There seemed to have been some antecedent chronic nephritis, and this was supported by the somewhat hypertrophied heart

On looking back over the somewhat inadequate clinical records of this case it was found that the daily urinary output had fallen from 950 c cm on the day after treatment was begun to 350 c cm two days before death little or none being recorded for the ensuing period There had been no gross hæmaturia and until the last two days no symptoms specially pointing to urinary involvement Unfortunately no investigations of renal function had been made

DISCUSSION

The relatively few instances of urinary complications recorded in connexion with the now large number of reports on M & B 693 treatment makes one consider the possibility of a special susceptibility in Melanesian natives As however these patients were treated under conditions which made it difficult to ensure an adequate fluid intake and no very systematic attempt was made to maintain a proper acid base equilibrium, further observations will be needed before assuming that there is any inherent difference in their capacity to conjugate the drug and excrete it in such concentrated form It has been shown

that the urine of such patients is highly acid (pH6 or less) and that the crystals are readily soluble in alkalis, so that it seems rational to adopt measures that will dilute and alkalinise the urine as a preventive

SUMMARY

In 109 cases of pneumonia in Melanesian natives treated with M. & B. 693 hæmaturia was found 13 times The hæmaturia was as a rule associated with characteristic crystals in the urine which were identified as a conjugated derivative of M & B 693. The suggestion is made that the hæmaturia is mechanical rather than toxic.

In a case without hæmaturia small calculi were found obstructing both ureters.

Fluids and alkalis should be given liberally when treatment with M. & B. 693 is adopted to prevent the deposition of crystals.

I am indebted to Dr E. T. Brennan, director of public health, Rabaul, for permission to publish this communication.

LOBSTERS AND GASTRO-ENTERITIS

SOME EXPERIMENTS ON COOKING AND STERILISATION

BY H. M. ROYDS JONES, M.D. Lond.
SURGEON, S.S. *Orion*, ORIENT STEAM NAVIGATION COMPANY

THE lay public is only too ready to blame shellfish for gastric upsets. Yet references to gastro-enteritis caused by lobsters are rare. Faidherbe (1904) describes two typical cases, and Stcherbak (1907) describes one case, which was followed by polyneuritis LaFavre (1930) reports an outbreak on the U.S.S. *Patoka*, due apparently to crawfish infected with salmonella organisms I myself have previously described two epidemics, the first of 152 patients, and the second of 49 (Royds Jones 1938). The lobsters responsible in the second outbreak were placed alive in boiling water, cooked for approximately forty minutes as they were "of large size," and served without being placed in cold storage After the claws were cut off, the body was split longitudinally. The gut was then removed by the cook's fingers and the body cut up by him into portions for service.

I suggested that if the lobsters had previously fed in contaminated waters and if the cooking had been insufficient to sterilise the gut completely, any bacteria in the intestine might have been transferred by the cook's fingers to the flesh, and thus to the patients To test this theory, 6 lobsters, from the same consignment and cooked at the same time were dissected and their intestines removed, minced, placed in broth and incubated *B. coli* and *B. proteus* were isolated Prof J. W. H. Eyre repeated the experiment with another 6 of these lobsters, and on investigating each intestine separately, he recovered *B. coli*, *B. proteus*, and *B. lactis aerogenes* from three, while the other three proved sterile

OBJECT OF EXPERIMENTS

The experiments reported here were undertaken firstly to find the time of cooking necessary to sterilise the intestine of the lobster, and to see whether or no this spoiled the lobster for eating, and secondly to ascertain the temperature to which the gut of the lobster is raised by different periods of boiling

There are two methods of cooking lobsters; they may be placed in cold water and brought gradually to the boil as recommended by the Royal Society for the Prevention of Cruelty to Animals (Sinel 1937) and frequently carried out in France, or they may be plunged alive into boiling water. I made inquiries at big fish restaurants in London and at a large wholesale fishmonger's in Billingsgate, and the second method seems to be the one commonly used over here. This was therefore adopted for the experiments. Each lobster was weighed and only those between 1½ and 2 lb. were used for the first series of experiments The thickness of the shell cannot be controlled, since it depends on the time since the last carapace was shed.

STERILISING LOBSTERS

Batches of lobsters were placed alive in boiling water and cooked for varying periods, the time being taken from when the water returned to the boil Each intestine was then dissected out with sterile precautions, minced into a broth tube, incubated and plated out on Conradi-Drigalsky medium. From this, colonies were "fished," grown on agar slopes, and examined for motility, Gram staining, and fermentation of lactose, glucose, saccharose, mannite, and dulcite. A growth of organisms obtained in this way gives no indication of how heavily the gut remained infected, but only shows that at least some micro-organisms in that intestine had survived the cooking During these experiments 65 lobsters' intestines were examined, and the results are shown in table I From all intestines recorded as showing growth in the table, Gram-negative bacilli were isolated, giving colonies on Conradi-Drigalsky medium similar in appearance to the coli-aerogenes group Some gave the reactions of *B. coli communior*, some of *B. coli anaerogenes*, some of *B. lactis aerogenes*, and others gave variations in sugar reactions from the common types belonging to this group.

TABLE I

(A) = Experiment number
(B) = Lobsters (L) used
(C) = Duration of boiling in minutes
(D) = Bacteriological result shown as number of intestines giving growth

(A)	(B)	(C)	(D)	(A)	(B)	(C)	(D)
1	5	20	4	5*	12 {6 L, 6 L}	35, 75	3, Nil
2	6	25	5				
3	6	35	6	6*	18 {6 L, 6 L, 6 L}	30, 45, 60	Nil, Nil, Nil
4	6	45	Nil				
				7*	12 {6 L, 6 L}	25, 45	3, Nil

* *In these last three experiments all the lobsters in each experiment were put into boiling water together, and batches were taken out at the times shown*

It appears from table I that 45 minutes' boiling usually suffices to sterilise the intestine of a 2 lb. lobster. In my opinion this is not long enough to upset the taste and palatability of the flesh. In restaurants and among wholesale fishmongers, the average time allowed for a 2 lb. lobster appears to be 25 to 30 minutes' boiling. From the bacteriological point of view, this would seem to be insufficient.

HOW HOT DOES A LOBSTER GET?

The temperature in the centre of a joint of meat does not rise to near boiling-point even after prolonged cooking (Thompson 1901). I can find no information about the temperature reached by the flesh of the lobster after different periods of immersion in boiling water. I therefore performed three experiments with 21 lobsters. The procedure adopted was to plunge the lobsters into boiling water simultaneously, and

to take them out one at a time at known intervals, break the head off the body, and thrust two thermometers into the interior of the flesh, taking the lower reading No allowance was made for the cooling of the lobster after removal from the water or for the coolness of the thermometer itself, but it is probable that the heat thus lost was small The findings are shown in table II These experiments show that the

TABLE II

(A) = Experiment number (B) = Lobsters used and weight
(C) = Duration of boiling in minutes
(D) = Temperature in degrees centigrade

(A)	(B)	(C)	(D)	(A)	(B)	(C)	(D)
1	5 (1 lb 4 oz each)	10	82·0	3	11 (2 lb each)	5	60 0
		15	84 5			10	76 5
		20	86 5			15	76 5
		25	85 5			20	82·0
		30	89 0			25	87 5
2	5 (2 lb each)	25	79 0			30	82·0
		35	91 0			35	90 5
		40	87·5			40	85·0
		47	90 0			45	90 5
		60	91·0			55	95 5
						75	95 5

temperature in the centre of the larger lobsters takes about 45 min to rise to the neighbourhood of boiling-point This probably accounts for the prolonged cooking necessary to sterilise the intestinal canal

SUMMARY

1 Cooked lobsters have sometimes caused gastro enteritis

2 Pathogenic organisms are probably carried from the gut of the lobster to the flesh by the cook during preparation for serving

3 If a 2 lb lobster is cooked in boiling water for 45 minutes instead of the usual 25 or 30 minutes, the gut is satisfactorily sterilised, and the taste is not appreciably affected

4 The internal temperature of a large lobster does not approach boiling point until it has been boiled for 45 minutes

5 If there is doubt about how long lobsters have been cooked, it is safer to eat small 1 lb lobsters, which are presumably more easily sterilised, or to confine oneself to the claws, or to recooked lobsters (for example "Lobster Cardinal")

I wish to thank Dr J E McCartney of the Southern Group Laboratory, London, for providing all the media for these experiments, except those for experiment 5, table I This experiment I carried out by courtesy of Dr Arthur Davies at his laboratory at the Seamen's Hospital, Greenwich, with media provided by him I have to thank Mr W A. Bennett of J Bennett (Billingsgate) Ltd , wholesale fishmongers, for supplying the lobsters used in these experiments

CLINICAL NOTES

GRANULOPENIA FOLLOWING ADMINISTRATION OF M & B 693

BY G O A BRIGGS, M B Camb , M R C P , D P H
DEPUTY MEDICAL SUPERINTENDENT OF LEICESTER ISOLATION HOSPITAL

Two patients with puerperal pyrexia were recently admitted to the Leicester Isolation Hospital on the same day Both had heavy uterine infections, though no pathogenic organisms were isolated Both were given M & B 693, developed rashes and granulopenia, and recovered

CASE RECORDS

CASE 1.—A multipara, aged 27, with a history of a previous attack of puerperal pyrexia, was admitted on the eighth day of the puerperium. She had been delivered of twins before the midwife's arrival and had had a severe postpartum hæmorrhage She was distinctly anæmic (hæmoglobin 20 per cent) and had a heavy uterine infection, blood-culture being sterile.

* Transfusion † Pentnucleotide started

M & B 693 was given by mouth in daily doses of 9 g at first and 6 g later, and the anæmia was treated with iron and a blood-transfusion of 500 c cm The temperature fell to normal in a week but rose two days later coincident with the appearance of a scarlatiniform rash (fig 1) Since this appeared to be a drug rash and the white-cell count had dropped from 67,300 to 15,700, the administration of M & B 693 was stopped 60 g having been given in nine days

A week later, although the temperature had become normal and the patient looked and felt well and the hæmoglobin percentage continued to rise, the white-cell count had fallen to 3600 of which 396 (11 per cent) only were polymorphs Intramuscular injections of 20 c.cm of Pentnucleotide were then given daily and a transfusion of 500 c cm of blood, but the polymorph count fell further to 156 (4 per cent of total white-cell count), though the hæmoglobin percentage continued to rise The first rise in the number of polymorphs was not registered till seven

days after starting the administration of pentnucleotide and four days after the transfusion Progress after this was rapid and uneventful (table I).

CASE 2.—A multipara, aged 41, was admitted on the eighth day of the puerperium after a normal labour. There was a heavy local infection of the uterus, blood-culture was sterile, and the general condition was good. M & B. 693 was given in daily doses of 6 g at first and 3 g later. After 42 g. had been given

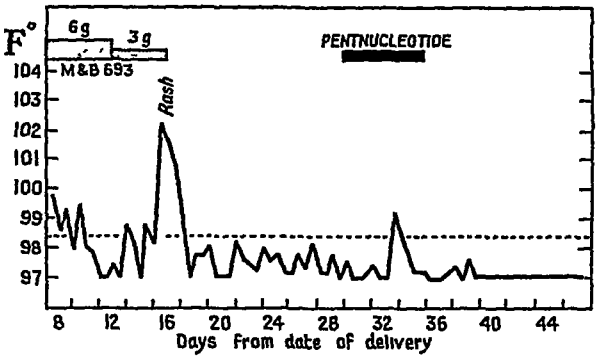

FIG. 2—Temperature chart in case 2.

in nine days, administration of the drug was stopped owing to the appearance of a morbilliform rash, obviously a drug rash (fig. 2).

The white-cell count, which had been initially 8500, was found ten days later to have dropped to 5800, of which only 1392 (24 per cent) were polymorphs. Two days later a course of intramuscular injections of 20 c.cm. of pentnucleotide was started and continued for five days, but a white-cell count made the same day as the administration of pentnucleotide was started showed the polymorphs to have already risen to 2709 (43 per cent of a white-cell count of 6300) Further recovery was uneventful (see table II).

COMMENT AND CONCLUSIONS

The occurrence of a rash on the eighth day of administration of M. & B. 693 agrees with Thompson's (1939) findings as to time of onset of rash The discontinuance of administration of M. & B. 693 did not prevent the development of granulopenia a week later in both cases, as has also been found by Sutherland (1939)

Pentnucleotide had no observable influence on the course of the granulopenia, the polymorph count in case 1 showing no improvement till seven days after the start of its administration, whereas in case 2 the count was already rising when treatment was begun. In this our findings do not agree with Crofton (1939)

Blood-transfusion was only given in case 1, and the polymorph count did not improve till four days had elapsed Nevertheless transfusion may be a useful means of tiding the patient over a period of danger.

The difference in the severity of granulopenia in the two cases may be partly accounted for by case 1 having received 60 g of M. & B. 693 in nine days, whereas case 2 only received 42 g. in the same time If so, this agrees with Sutherland's (1939) suggestion that quantities over 50 g. may be dangerous to patients already suffering from a disease which causes some destruction of blood corpuscles

Granulopenia is a definite and dangerous complication associated with the administration of M & B. 693 The drug should not be given in massive doses without adequate control by examinations of the blood. The appearance of a rash is an additional indication for further investigation of the blood

My thanks are due to Dr. J. C H. Mackenzie, medical superintendent, for permission to publish these cases and for helpful criticism, and to Dr. E M. Ward for pathological investigations.

PRIMARY FIBROSARCOMA OF THE HEART

REPORT OF A CASE

BY MARGARET NELSON JACKSON, B M Oxfd, D.P M

ASSISTANT MEDICAL OFFICER AT THE FOUNTAIN HOSPITAL, LONDON, AND

J N JACOBSON, M R.C.S, D P.M., D M R E

DEPUTY MEDICAL SUPERINTENDENT OF THE HOSPITAL

PRIMARY tumours of the heart are rare and generally cause no symptoms, only one such tumour has been diagnosed during life. About 80 per cent of the tumours reported have been benign. Of 143 cases collected by Mandelstamm (1923) 117 were benign and 26 were malignant Most of the benign tumours were myxomata and most of the malignant tumours sarcomata Fibrosarcomata are less common than many other varieties of sarcoma; of the 230 primary heart tumours reported by Lymburner (1934) 57 were sarcomata and none fibrosarcoma Yates (1931), analysing 45 reported cases of sarcomata, found that only 3 were fibrosarcomata; round-celled and spindle-celled tumours made up three-quarters of his series

Primary sarcomata of the heart are not usually associated with developmental defects as are the rhabdomyomata, but Fidler, Kissane, and Koons (1937) reported a case of cardiac fibrosarcoma in a boy, aged 9 months, who also had hare-lip, cleft palate, and double inguinal hernia. Four other such tumours have been reported by Popp (1932), Raw (1898),

FIG. 1—Macroscopic appearance of fibrosarcoma on section of the heart.

Jürgens (1891), and Ericsson (1908) in patients whose ages ranged from 33 to 43 years None of these patients showed developmental defects, and the tumour was discovered at autopsy in each case

In our case there were mental defect and developmental anomalies besides the tumour of the heart

FIG 2—Microscopic section (low power) of fibrosarcoma of heart, showing dense interlacing fibrous tissue

The patient was a microcephalic girl of idiot grade, aged 9 years She was diplegic, with adductor spasm of the legs, spastic arms, and postural scoliosis Her face was asymmetrical, the right side being larger than the left She had internal strabismus and bilateral optic atrophy There was no clinical evidence of abnormality of the heart She died in November, 1937, of pneumonia and pneumococcal meningitis

Necropsy.—Her brain (weighing 23½ oz.) was the typically small brain of the microcephalic Purulent exudate containing pneumococci covered the outer and inferior surfaces of the frontal lobes On section of the brain the corpus callosum was found to be absent The right lung showed advanced bronchopneumonia of the lower lobe The kidneys were slightly lobulated

There were no other abnormal features except in the heart The pericardium contained a slight excess of clear straw coloured fluid The heart weighed 4½ oz and the left ventricle appeared to be enlarged On section a white rounded tumour, measuring about 1 × 1½ in., was found in the left ventricular wall, near the apex of the heart (fig 1) The tumour, thinly covered by myocardium, bulged into the left ventricle and occupied about half of the cavity It pressed against the interventricular septum, deflecting it and causing it to bulge into the right ventricle The tumour occupied only the apical tissue of the left ventricular wall, which covered it like a thin shell At the apex of the heart the muscle covering the tumour was about ⅛ in thick and was pale

Under the low power of the microscope sections of the tumour showed dense fibrous tissue arranged in long interlacing strands (fig 2) At the border irregular finger-like processes of fibrous tissue extended from the tumour into the heart muscle, especially in the neighbourhood of blood vessels Under a higher power the tumour cells appeared fibroblastic in type, with plump elongated nuclei At the borders of the tumour fibroblastic cells could be seen interpenetrating the heart muscle fibres, replacing them, and forming cuffs about the blood vessels In the peripheries of the tumour were many cells with irregular nuclei, fibrosarcomatous in type

We wish to thank Dr J I S Lloyd, medical superintendent of the Fountain Hospital, for his kind permission to publish this case

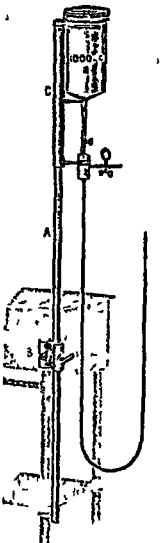
New Inventions

STAND FOR INTRAVENOUS THERAPY

THE majority of "intravenous" stands for suspending the container when giving a blood transfusion or intravenous saline consist of some form of tripod with a hook-like upper extremity from which the container is slung by a metal ring and bucket handle This is a very unstable piece of apparatus, for the tripod may be knocked out of position by anyone passing the foot of the bed and the container swings precariously in the air This pattern of stand also is difficult to transport from operating theatre to ward



The stand shown in the figure consists of (A) a hollow steel rod 4 ft long and slotted at its upper end, (B) a universal clamp by which the rod may be attached to a bed, side table, or theatre trolley, and (C) a frame for holding the container The frame is a hollow cylinder carrying two or three incomplete metal rings, with a transverse bar at its upper end which fits into the slot on the top of the steel upright A spring clip, like a trouser clip, may be used instead of the upper metal ring on the frame This prevents any rattling and also allows for small variations in the size of the necks of the containers In my experience it does not stretch or lose its spring In the pattern in use at St George's Hospital, London, there is an additional spring clip attached to the lower extremity of the frame This is to hold the visible feed (glass dropper with side arm)

The height of the container can be varied by adjusting the rod in the clamp The glass container advised is of two pints capacity; the more usual four-pint size is larger than necessary for the average transfusion and clumsy to manipulate The Ministry of Health bottles provided in the emergency transfusion sets which have recently been distributed to civilian hospitals can readily be slung by their wire handle from the upper end of the slotted rod If the rotary pump is being used the platform on which this is mounted carries a small fitting which enables the transfusion unit to be carried by the steel upright

This type of stand is light, it is interchangeable between operating table theatre trolley and patient's bed, and it is stable It is an advance on any other type I have seen or used

The makers are the Genito Urinary Mfg Co Devonshire Street, London

MEDICAL SOCIETIES

BRITISH MEDICAL ASSOCIATION

SECTION OF MEDICINE

AT a meeting of this section, with Dr. A. GREIG ANDERSON (Aberdeen), the president, in the chair, a discussion on the

Medical Treatment of Peptic Ulcer

was opened by PROF. EINAR MEULENGRACHT (Copenhagen). He began with the treatment of bleeding ulcer, because the experience obtained with a free diet has influenced his outlook on the treatment of ulcer in general. From 1931 onwards he has treated all his cases of hæmatemesis and melæna from the first day "with food" The diet has been varied and liberal consisting of soft and non-irritating foods —the so-called purée diet—and fluids have been allowed as desired. Up to the beginning of this year 491 cases of profusely bleeding ulcer have been treated in this way. Cases of hæmorrhage from cancer of the digestive canal and from cirrhosis of the liver were not included He has found that (1) patients, doctors and nurses like the treatment; (2) the food in the stomach does not increase or protract the bleeding; (3) post-hæmorrhagic shock is diminished or not noticed at all, (4) strength is regained more quickly; (5) blood regeneration is more rapid; (6) convalescence is shortened; and (7) the mortality in this series was between 1 and 2 per cent Nausea should not be a contra-indication to this form of treatment, since the food usually relieves nausea by causing the stomach to empty itself of blood. The treatment is unlikely to be successful if it is applied hesitantly; indeed, the more severe the hæmorrhage the more urgent is the patient's need for fluid and food. Professor Meulengracht does not advise operation to check bleeding, but blood-transfusions are indicated in dangerously ill patients. He admitted that it is difficult to compare his results with those obtained in England with the usual strict regime, but he said that a mortality of 7–9 per cent is still usual in Denmark when the older type of treatment is used

Lean, over-active men who do not give enough time to meals are especially prone to the development of peptic ulcer and the nervous element is important as an ætiological factor The fundamental principles of treatment are, therefore, rest, relaxation and a calmer outlook on life As a result of experience with bleeding ulcers, Professor Meulengracht has adopted a freer dietary regime in cases without hæmorrhage—i.e., soft non-irritating food taken liberally and often. The diet must be sufficient not only in quantity but also in quality, and must contain the necessary amounts of vitamins and salts. He considers that the use of alkalis and belladonna is advisable but not of paramount importance

Dr. T. L. HARDY (Birmingham) agreed with the plea for a more liberal diet in uncomplicated cases, but he himself has not extended this as far as Professor Meulengracht. Most patients admitted to hospital are, he said, in a state of mild under-nutrition and vitamin-C deficiency is common. Convalescence is considerably shorter when a generous diet is given than when the patient is restricted to small quantities of milk and cereals over a long period. Patients should be made thoroughly conversant with the details of treatment while in hospital, because a life-long policy rather than a short-term one is essential if recurrences are to be avoided Those liable to the disease are restless, energetic and hard-working people. Complete rest in bed for at least a month is therefore indicated, ambulatory treatment being unsuccessful in the great majority of cases. It is the duty of the doctor to inquire fully into the daily routine of each patient and to suggest modifications which will relieve mental and physical strain Peptic ulceration is often activated during times of overwork and this fact increases the difficulty of instituting proper treatment by rest in bed. In Dr Hardy's view small doses of sedative drugs such as phenobarbitone are of more value in treatment than alkalis. Tobacco and alcohol should be forbidden during the strict stage of treatment but may be allowed in small quantities later as a concession to human frailty.

Dr. ARTHUR LEESE (Oxford) described the results of balance experiments on patients with gastro-intestinal hæmorrhage. The rise in blood-urea which follows hæmorrhage may be due to three factors—(1) a breaking down of body proteins; (2) absorption of nitrogen from the bowel, and (3) a temporary renal impairment. In view of the first of these factors a liberal diet containing adequate protein is an important part of treatment.

Dr. T N. MORGAN (Aberdeen) dealt with the metabolic changes after severe hæmorrhage from peptic ulceration. Renal function is reduced as a result of diminished blood-volume and low blood-pressure The urea in the blood, derived from the nitrogen absorbed from the bowel and from the utilisation of body protein, therefore rises to high levels. The high blood content of urea then acts as a diuretic and tends to decrease still further the body fluids These considerations support Professor Meulengracht's plea for a liberal diet and unrestricted fluid intake in cases of hæmorrhage

Dr. B M NICOL (Aberdeen) discussed the effects of different diets and drugs on the mean free gastric acidity. In patients with peptic ulcer samples of the gastric contents were aspirated at intervals over periods of twenty-four hours Three types of diet were used: (1) small milk feeds hourly; (2) a similar diet given at two-hourly intervals; and (3) a light ward diet The mean free gastric acidities were 61, 39 and 47 units respectively Gastric acidity can be controlled if milk is dripped continuously into the stomach at the rate of 5 oz. each hour. This indicates that the failure of an hourly feed of 5 oz. of milk to control the acidity is due to the fact that the milk is rapidly expelled from the stomach. Atropine gr. $\frac{1}{60}$ four-hourly, given in addition to feeds every two hours, make little difference to the acidity, and Dr. Nicol obtained similar results when large doses of magnesium trisilicate and aluminium hydroxide were given. He concluded that two-hourly feeds of high protein value probably constituted the best form of diet therapy. Atropine should be used only if symptoms suggesting pyloric spasm are present, and in such cases the dosage should be pushed to the limit of tolerance The importance of high gastric acidity in preventing healing may be exaggerated, since healing apparently takes place satisfactorily in spite of a high mean acidity provided that the patient is kept at rest in bed.

Dr S W. PATTERSON (Ruthin Castle) outlined the routine treatment given at Ruthin Castle Rest in bed for at least a month, proper cleansing of the mouth and attention to the teeth, the avoidance of tobacco, and the administration of alkalis are factors

of importance in promoting healing The diet in the early stages consists of 4–10 oz of milk with or without egg, given every three hours and sipped slowly throughout this period A rise in gastric acidity and stretching of the ulcer are avoided by this method of treatment

Dr J JACQUES SPIRA (London) said that it is essential to differentiate clearly between acute and chronic peptic ulcers Acute ulcers are often multiple, are either fatal or heal rapidly, and probably have a systemic origin Chronic ulcers, on the other hand, are always single and produced by a local inflammatory process An acute ulcer never becomes chronic and a chronic ulcer never becomes acute Dr Spira then outlined his theory of the ætiology of chronic ulceration Gastric peristalsis is normally uni directional, and therefore the function of the pylorus is to prevent the regurgitation of duodenal contents into the stomach The presence of fat in the stomach brings about regurgitation, and the association of bile and hydrochloric acid then produces gastritis with hypertonus and hypersecretion The logical treatment is to give alkalis to control the acidity and to prescribe a fat free diet—1 c, one containing no visible fat and without milk and eggs

Dr A T M WILSON (London) said that patients who develop peptic ulceration react with a bodily and mental disturbance of a particular pattern leading to gastric dysfunction when driven or led into situations capable of producing emotional states Such patients should therefore understand thoroughly the connexion between emotional and gastric upsets Some of them tend to resist the idea and some form of psychological treatment is then both necessary and effective

Dr LAURENCE SCOTT (Glasgow) said that there is marked and immediate benefit when cases of hæmatemesis are treated on the lines laid down by Professor Meulengracht, but one cannot expect much benefit from the administration of a purée diet alone when the lesion is very severe—e g causing erosion of the pancreas

Prof L S P DAVIDSON (Edinburgh) said that the treatment of bleeding ulcer has now been placed on a satisfactory basis since any well balanced non irritating diet given two hourly together with mental and physical rest, produces healing in the great majority of cases Operation to control hæmorrhage should not be resorted to until not less than three or four blood-transfusions have failed If this rule is adhered to the indications for operation are very rare Professor Davidson suggested that ambulatory treatment may be preferable to complete rest for those patients with non bleeding ulcer who worry greatly if they cannot give at least some attention to their business

Prof R S AITKEN (Aberdeen) said that it is wrong for ambulatory patients to take atropine for the sole purpose of relieving pain Pain should be a warning that the patient is driving himself too hard, and its proper treatment is more rest

Mr HAROLD DODD (London) referred to the rôle of surgery in the treatment of peptic ulcer Some patients lead miserable lives because of recurrent attacks of pain which are not relieved by strict attention to the usual regime In such cases operation is often successful and enables the patient to adopt a higher scale of living He believes also that removal of septic foci gives complete relief in a fair proportion of cases

Dr A GILLIS ANDERSON (Aberdeen) discussed the relationship between the site of a gastric ulcer and the type of treatment which should be adopted The chances of malignancy in ulcers on the greater curvature are so great that all such cases should be explored surgically as soon as possible There is also a definite tendency to malignant changes in ulcers of the pyloric antrum, and in these medical treatment should therefore not be continued for more than three or four weeks unless there is conclusive evidence of healing Ulcers of the pars media in the region of the lesser curvature rarely become malignant and should be treated medically under radiological control.

SECTION OF ORTHOPÆDICS

AT a meeting of this section with Mr ALEXANDER MITCHELL (Aberdeen) in the chair, a discussion was held on

The Painful Shoulder

Dr PHILIP DUNCAN WILSON (New York) spoke of 168 cases of shoulder pain personally studied He suggested that as lesions round the shoulder-joint had a varied and vague pathology any classification must be on an anatomical basis In his series lesions of the subacromial bursa made up 53 per cent The bursa was particularly important in especially abduction and rotation He agreed with Codman that often disease in the underlying avascular supraspinatus tendon was the cause of symptoms which were more evident in the more vascular subacromial bursa Calcifying tendinitis was quite often a cause of pain The deposit of calcium was visible on X ray in the supraspinatus tendon, but sometimes as much or more was seen in the contra lateral and symptomless shoulder In some cases the deposit continued into the insertion in the greater tuberosity of the humerus The material seen at operation varied in consistency from gritty particles to something like white toothpaste, and might even be mistaken for pus Similar deposits have been described in gluteus medius, flexor carpi radialis and the tendo achillis Microscopically, the deposit was first seen in small circumscribed areas in the tendon fibres These enlarged and worked their way to the surface of the tendons, and later on all the changes of acute inflammation might be found The origin was obscure but was possibly due to the deposit of calcium salts in already degenerating cells When the affected tissue was still deep to the tendinous structures there was no pain until the mass bulged outwards sufficiently to impinge on the acromion process on abduction This was the subacute phase and an X ray taken then would show the early lesion The acute phase was characterised by sudden very severe pain in the shoulder with redness and tenderness below the acromion process In some cases, the mass had ruptured into the subacromial bursa which contained calcified material and fibrin Treatment with rest and physical therapy was sometimes followed by relief and X-ray improvement, but surgical excision always gave a good result But in the subacute stage patients were unwilling to have an operation, and fortunately aspiration and irrigation through wide bore needles was very satisfactory Occasionally the deposit was too solid for aspiration and operation was then the method of choice

Periarticular adhesions were another common cause of shoulder pain They occurred in rather older people and were commoner in males There was no clear cut pathology but symptoms were more definite These were limited and painful abduction and rotation of the arm, often accompanied by night

pain. X ray did not reveal any abnormality other than occasional flecks of calcification in the joint-capsule The treatment was manipulation, usually under an anæsthetic Foci of infection could not be blamed for the condition, nor was the disease self-limiting. Physical therapy, pendulum exercises, manipulation, and arm-suspension did a great deal to shorten the disease Adhesive traction applied to the suspended arm, with the elbow flexed to a right angle, was of particular value in undoing the painful muscular spasm which frequently followed vigorous manipulation

Mr. V. H. ELLIS (London) agreed about the difficulty of classification, and confined his attention to lesions of the supraspinatus tendon. These may be contusion, partial or complete rupture and degeneration Trauma was commonest in manual labourers and was usually a fall on the abducted arm. On examination, passive movement of the shoulder was full, but pain was felt when the supraspinatus insertion was passing under the acromion process Active abduction was limited beyond 20 or 30 degrees Pain was felt over the greater tuberosity, and at the insertion of the deltoid. This pain was much more severe than that felt in dislocations or fractures of the greater tuberosity. With complete tears, the symptoms were similar for a few days, but after that time movement of the humeral head did not return on electrical stimulation of the supraspinatus muscle as it did with partial tears Later on there might be wasting in the supraspinous fossa In most cases not treated by operation healing was the exception, especially where there was a degenerative element present The best operative exposure was through the anterior fibres of the deltoid There was no difficulty in exposing complete tears, but partial tears were less easy to identify. The period of convalescence was, about three months if passive movements were started early

Mr. B. L MCFARLAND (Liverpool) stressed the usefulness of the aspiration of calcifying tendinitis, and of pendulum exercises as an after-treatment of shoulder lesions He adopted a practical clinical classification :—

(1) Cases where there is no limitation of movement —i e , where the lesion is outside the joint. (*a*) where movement does not affect pain ; (*b*) where movement does affect pain

(2) Cases where there is limitation of movement : (*a*) limitation similar in all directions ; (*b*) limitation mostly in one direction.

Where there was no limitation of movement, and movement did not affect pain, the pain was referred from some outside source—e g., the heart or the cervical spine. Where movement did affect the pain, there were usually some changes overlying the joint—e g , fibrositis or tenosynovitis. Where movement was limited in all directions equally, the cause was probably some form of arthritis Lastly where movement was limited in one direction only, there were only three likely causes : lesions of the supraspinatus tendon, adhesions, and calcifying bursitis. Calcifying bursitis and supraspinatus injuries were closely allied. It was possible that there was a condition in the long tendon of biceps allied to trigger-finger, which might give rise to similar symptoms Adhesions in the shoulder-joint were very common, and were caused by trauma, exposure, strained posture or bad position during breast and other operations. In manipulation two kinds of adhesions were obvious to the trained ear, those which tore and those which snapped. Those which snapped were the single massive adhesions which limited movement in one direction, and they had a better prospect of recovery than cases with multiple smaller adhesions

Mr. H O. CLARKE (Manchester) praised the two-needle technique of aspirating calcifying tendinitis He mentioned the occurrence of shoulder stiffness in patients recovering from acute febrile illnesses, and stressed the value of manipulations repeated at weekly intervals and with increasing ranges of movement at each manipulation. He personally had difficulty in identifying tears in the supraspinatus tendon at operation

Dr. BREBNER SCOTT (London) said that he had had a painful shoulder for some time and agreed that the suspended position gave some relief. Otherwise he thought that time had been the most important factor in his recovery. Dr. GERALD SLOT (London) thought that pain ought to be treated as a disease rather than as a symptom, and recommended massive and repeated injections of novocain into muscles in spasm round a painful joint He liked pentothal anæsthesia for manipulations and thought that gold injections were valuable in some cases / Mr H J MCCURRICH (Hove) also had a painful shoulder which he ascribed to continual driving of his car in all weathers He wondered if pain in the left shoulder was commoner in America, where drivers exposed the left side.

Mr D. MCVICKER (Belfast) said he could often elicit a history of pain before the alleged injury, and laid stress on diet as a possible line of treatment He did not favour anæsthesia for manipulations, preferring repeated movements to the limit of tolerance. Mr H. POSTON (Manchester) did not think focal sepsis was important He believed snapping adhesions were intra-articular and the tearing type were extra-articular. Working in an area where calcium deficiency was common, he did not often see cases of supraspinatus calcification. Miss M. F. FORRESTER-BROWN (Bath) pressed the claims of spa treatment combined with other measures

Mr. V H. ELLIS admitted the difficulty of identifying the tear in the supraspinatus tendon at operation and agreed that it was very much easier if treatment were started early. Mr. B. L MCFARLAND had seen several cases where shoulder stiffness had occurred after acute illnesses. Repeated small manipulations were useful, especially where there were multiple adhesions, but he always preferred to have the patient under an anæsthetic.

"A hospital is intended primarily and ultimately for the medical treatment of the sick, all its other services are subsidiary to this, its main, purpose. Only a medical man who has spent at least six years in acquiring his knowledge can guide a hospital efficiently, for he alone can have knowledge of the medical side of the work for which the hospital was established. Only a medical man can by his training realize the relative value of the medical needs of an institution Only a medical man can discuss on terms of equal understanding with his seniors and fellows, the members of the honorary staff, necessary progress and expansion. Only a medical man can supervise the work of the medical staff Since the treatment of the sick is all important in the life of a hospital, and since none but a person trained in medicine can understand this treatment, it follows that the control of a hospital should not be entrusted to a layman who has not sufficient knowledge to give judgement on a medical problem, and who is apt to allow the side that he knows, the business side, to override the side that he does not know. Control of a hospital entrusted to a layman is like the navigation of a ship given into the hands of its purser."

REVIEWS AND NOTICES OF BOOKS

Sexual Disorders in the Male

By KENNETH WALKER, F R C S, surgeon to the genito-urinary department, Royal Northern Hospital, and to St Paul's Hospital, London, and ERIC B STRAUSS, D M Oxfd F R C P, physician for psychological medicine to St Bartholomew's Hospital, and physician to the Tavistock Clinic, London London Hamish Hamilton Medical Books 1939 Pp 248 10s 6d

THIS short volume, which has been completely revised and supplemented by an account of the psychological aspect of sexual disorders, is intended for the general practitioner and senior medical student, and as such will be welcomed For sexual education is so neglected that even many doctors and students are vague as to the normal functions of sex, to say nothing of its disorders The book ably points out the psychological conditions, conflicts and the like which arise through ignorance of the primary facts of life and may lead to impotence, ejaculatio præcox, sexual deviations and a variety of other disorders The authors outline their causation and treatment, but surely the real solution of these difficulties lies in prevention through the sensible instruction of every one before marriage Wedlock is an art which, like any other, must be based on knowledge, whereas any couple can now try to set in motion a highly sensitive chain of nervous reflexes without any instruction whatsoever

Impotence necessarily takes up much of the book Masturbation is dealt with sensibly, its part in the normal development of sex and its usual harmlessness are explained The authors plead for an alteration of the law which still regards homosexuality as a crime, and their arguments might well be read by members of the bench Their remarks on the endocrine treatment of the enlarged prostate are wisely restrained, but too little is said of therapy with testosterone propionate for various other disorders of the male Many failures with this drug must be due as Mr Kenneth Walker says, to insufficient dosage

The book will help the practitioner to rectify some of the damage resulting from ignorance in those less reticent patients who seek his advice

Short Textbook of Surgery

(2nd ed) By C F W ILLIS WORTH, M D Edin, F R C S E, lecturer in clinical surgery, University of Edinburgh, assistant surgeon, Edinburgh Western Hospital London J and A Churchill 1939 Pp 707 21s

THAT a second edition of this excellent textbook has been called for within a year is a striking tribute to its popularity amongst students This is understandable, for the subject has been skilfully condensed without the necessity for many omissions In this edition new matter has been added on the treatment of jaundiced patients, sympathectomy and the use of sulphanilamide It does not seem quite a fair presentation of the facts to say that 'sulphanilamide appears to be of some value" in *B coli* cystitis, nor does it seem advisable to state that presacral nerve section is employed for dysmenorrhœa without giving some indication of its serious drawbacks for this purpose But when all is said and done there remains very little for criticism There may be a few slips here and there as for example the erroneous statement that abscesses are situated at the root of the lung, when the author means near the mediastinal part of its periphery, but they are very few Particular praise may be accorded to the accounts of general subjects such as physiotherapy, postoperative complications, salt and water balance, renal function tests, diabetic surgery, all these are treated simply, clearly and sufficiently to give the undergraduate an intelligent grasp of them There are about 30 new illustrations The book has an established place which we predict will be maintained

Le Gastriti Croniche

By PAOLO ALESSANDRINI, senior physician to the United Hospitals of Rome 1939 Pp 275 Lire 15

Le Cefalee

By GIOACCHINO FUMAROLA, professor of neuropathology in the University of Rome 1939 Pp 101 Lire 15

Parassitosi Intestinali

By VITTORIO VANNI, director of the institute of medical parasitology of the University of Rome 1939 Pp 101 Lire 15

Diabete e Glicosurie non Diabetiche

By GIULIO C DOGLIOTTI, assistant to the institute of medical pathology and clinical methodology of the University of Florence 1939 Pp 212 Lire 15

THESE four monographs, published by A Valleccbi of Florence, form part of a series dealing with practical aspects of medical subjects, edited by Professor Frugoni of the University of Rome Without going deeply into their subjects they are designed to supply the general practitioner with a means of rapidly refreshing his memory and bringing his knowledge up to date Of these volumes Professor Dogliotti's (on diabetic and non diabetic glycosuria) is outstanding for the amount of information it contains and for the lucid way in which this information is presented Vanni's monograph on intestinal parasites summarises the essential points clearly, and is well illustrated Both these books include a small bibliography Headache, dealt with by Fumarola, is too large a subject to be satisfactorily compressed within the limits of this series, and the section on treatment is sketchy The monograph on chronic gastritis gives a brief description of recent advances in gastric pathology and the lines of treatment thereby opened up The series is pleasantly got up, of a handy size and easy to read The absence of an index, which is not unusual in foreign publications, is a source of annoyance to English readers

Pharmacology and Therapeutics of the Materia Medica

(15th ed) By WALTER J DILLING, M B Aberd, M P S (Hon), professor of pharmacology and general therapeutics, Liverpool University London Cassell and Company 1939 Pp 600 10s 6d

THE first edition of this book made its appearance in 1884 with Dr Mitchell Bruce as the author It achieved at once a wide popularity, reprints and fresh editions were published almost annually, and later the original author was joined by Professor Dilling Since then Bruce and Dilling's "Materia Medica and Therapeutics" has become known to students as an amazing collection of information upon the actions, methods of administration and therapeutic uses of drugs It now appears under a slightly changed title and with an improved format The book has been thoroughly revised, every modern remedy and method of treatment of proved value or of promise is included and adequately discussed The section on general pharma-

cology and therapeutics has been printed in larger type—a welcome improvement The book will continue to appeal to students and practitioners who wish to possess a full yet concise account of the modern therapeutical armamentarium.

Clinical Gastroenterology

By HORACE WENDELL SOPER, M.D, F.A.C.P, St. Louis, Missouri. London: Henry Kimpton. 1939. Pp. 314. 25s.

THIS is a book of moderate size and elegant appearance; not a systematic treatise on its subject, but, in the author's words, "a crystallisation of my clinical practice" He takes the ordinary textbook for granted, and in 30-odd chapters on as many gastro-intestinal topics sets forth his own interpretations of *his reading and experience* With much of what he says the orthodox physician would agree, and his style is forceful, suggesting a vigorous and confident personality. Sometimes he is more crisp than logical, as in this conclusion · "indicanuria (and such symptoms as may be attributable to it) is amenable to general dietetic and hygienic treatment, but the reaction in the urine remains four-plus regardless of improvement in the patient's condition" Sometimes he accepts whole-heartedly views which elsewhere have met with much criticism, such as the causation of ulcerative colitis by Bargen's bacillus and the efficacy of its treatment with his serum and vaccine. Elsewhere he attacks widely accepted views with surprising vehemence, especially where he condemns out of hand the drinking of raw milk because it may contain brucella, *Streptococcus viridans*, and streptococci producing peptic ulcer; pasteurisation doesn't sterilise, and is "but a gesture in the right direction", evaporated milk is the only form of milk that should ever be given to children or adults, sick or well. But such idiosyncrasies are mixed with a lot of sound clinical teaching, tersely put, and illustrated with nearly 200 beautiful radiograms.

Everyday Biology

An Introduction to the Study of Life. By G. PUGH SMITH, Ph.D., assistant lecturer in education, University College, Cardiff. London: G. Bell and Sons. 1939. Pp. 283 3s. 6d.

RARELY do writers of school biology books attempt to break away from two well-worn paths One is bounded by the examination syllabus and is concerned with the anatomy of types and a little plant physiology. The other is a disconnected series of little talks on the curiosities of nature To give a sound introduction to modern biology and its relation to human affairs which will appeal to children is no easy task. Dr. Smith has certainly achieved something, mainly because he has devised suitable practical work Excellent suggestions are made for simple experiments and observations on foodstuffs, development, growth, environment, and animal behaviour, apart from the usual dissections and experiments on plant physiology. Another serious difficulty, which the author has not so successfully surmounted, is that of presenting up-to-date conceptions in a small space without making unintelligible or unjustifiable statements. In his short introduction to experimental embryology the author refers to the chemical work on the "organiser," the significance of which is as yet debatable An extraordinary omission is the absence of any discussion on the significance of fertilisation and sex in the light of the facts given. The facts themselves are few; no mention is made of parthenogenesis, though a whole chapter is devoted to the principles of genetics The general tone is a little patronising "This chapter is not big enough nor are you old enough yet for me to tell you more about memory . . .," does not indicate a profound understanding of child psychology. In spite of its deficiencies the book contains much material not easily found elsewhere.

Diverticula and Diverticulitis of the Intestine

By HAROLD C. EDWARDS, M.S. Lond., F.R.C.S, *surgeon and lecturer in surgery to King's College Hospital, London.* Bristol. John Wright and Sons. 1939. Pp. 335. 25s.

THIS monograph is based on the Jacksonian Prize essay for the year 1932, and it has been revised and brought up to date Mr Gordon-Taylor in a foreword praises the author both for the thoroughness with which he has handled his subject and for having allowed seven years to elapse between writing the essay and publishing it in book form. It is this interval no doubt which accounts for the clinical insight and balanced judgment which are outstanding features of the work. The whole subject of intestinal diverticula both congenital and acquired is dealt with, and there is a wealth of illustrative pictures and case-histories The author merits thanks for having brought within one cover so much valuable information on a subject of interest to many branches of the medical profession

Evans' Recent Advances in Physiology

(6th ed.). Revised by W. H. NEWTON, M.D., M.Sc. Manc., reader in physiology in the University of London, at University College. London: J. and A. Churchill. 1939. Pp. 490. 15s.

THE sixth edition of this familiar book is Dr. Newton's second revision of it, and in his hands it still keeps its interesting and progressive character. There are three new chapters, on the physiology of bone, the Carrel-Lindbergh perfusion apparatus, and carbohydrate metabolism. The rest of the book is similar to the fifth edition, but has been fully revised. The chapter on the secretion of urine has been rearranged, and the section on defæcation has been omitted

The chapter on bone deals with its developmental architecture and describes the results of tissue-culture. The chemistry of the inorganic matrix is a little difficult for those who are not familiar with geological classification and X-ray spectrophotography. Blood-calcium and the problem of calcification are discussed, but the influence of vitamin D and the parathyroid are unfortunately omitted The account of the Carrel-Lindbergh perfusion apparatus is of doubtful value It is a new technique results of which are as yet not numerous Any student, who is sufficiently interested in the working details of the apparatus, would consult the authors' original papers and not the condensed account in this book.

Carbohydrate metabolism is becoming exceedingly complex and the chapter dealing with this is very welcome It begins with a reasoned consideration of the significance of the blood-sugar level, but the part dealing with the interplay of endocrine organs is too condensed to be clear. The style of this book is very pleasant. Although full references to modern work are included, the text is much more than a résumé of recent advances in knowledge The author outlines each problem and then leads his reader in orderly progress through the recent investigations This makes the great mass of information much more digestible It also gives a reasonable picture of the present position and some indication of the needs of the future

THE LANCET

LONDON SATURDAY SEPTEMBER 30, 1939

THE ULCER PATIENT

Two things were noteworthy in that meeting of the section of medicine of the British Medical Association at Aberdeen which discussed peptic ulcer, and which we report this week One was the personal impression made on the audience by Professor MEULENGRACHT He told his story crisply and simply, with no beating about the bush His attitude was a compound of keenness and sanity, set off by a faint touch of youthful bravado And his story was worth telling, familiar though it already is to many readers of the English medical journals His main point was that any patient who has bled rapidly from a peptic ulcer is almost certain to recover if he is given reasonable amounts of food and drink at once and frequently (an occasional case may need a blood transfusion), whereas if food and drink are withheld, whatever else is done, he runs an appreciable risk of dying It does not seem to matter much what food and drink is given, so long as it is easily assimilable and contains water, salts, vitamins and calories No special "Meulengracht diet" or "Watts diet" is called for, but simply food and drink, in bland form, as much as the patient will take The principle is plain and it is gaining rapid acceptance from those who apply it In their review in this issue of 241 consecutive cases of bleeding peptic ulcer treated in the Western Infirmary, Glasgow, GRAHAM, ALEXANDER and KERR record a striking fall in mortality accompanying the abolition of starvation and under feeding It is true that objections have been raised, but these have been based on theoretical fears We are not yet learned enough to forecast from theory whether the filled stomach will bleed more than the empty one, we must simply try and see Those who have not tried should do so, for the principle that Meulengracht has brought forward and re emphasised now stands established

For the rest, Professor Meulengracht summed up his treatment of the peptic-ulcer patient, bleeding aside, in the words "rest, relaxation, feeding", alkalis, belladonna and other procedures aimed at the local lesion were for him of less-er importance He paid tribute to the work of DAVIES and MACBETH WILSON, whose investigation of the psychology of ulcer patients had made the scales fall from his eyes" The second striking thing about the meeting was that nearly every speaker accepted the view that emotional factors are of prime importance in the genesis and therefore in the treatment of ulcer The thesis put forward by DAVIES and MACBETH WILSON in their new paper which we publish on another page is that the ulcer patient possesses all his life a certain kind of personality or psychological make-up, and that the development of his ulcer or ulcer-dyspepsia is determined by disturbing situations or events, especially those that threaten his economic security, increase his responsibility, or concern the members of his family The present paper tests the second part of the thesis on 50 cases of ulcer-hæmatemesis and 25 cases of ulcer-perforation, arguing that either of these complications is prima facie evidence of unusual activity of the ulcerative process, and showing that in the majority of the cases the bleeding or the perforation was shortly preceded by a major disturbance in the patient's personal life These case-histories make interesting reading, and they support the thesis well Most physicians will be able to add examples from their own experience, more often perhaps from among their friends and colleagues who have ulcers than from their hospital patients whose lives they know less well And most physicians will accept the views of DAVIES and WILSON as a crystallised and documented statement of what they themselves already appreciated in outline They will do so the more readily since the technique of this investigation is no subtle psychological mystery but simply that of the observant novelist freed from the need to disguise his sources

The psychosomatic connexion through which a financial crisis precipitates a hæmatemesis is still obscure There is experimental evidence that stimulation of the hypothalamic region can influence the movements and secretion of the stomach, but it has yet to be shown how human emotional states do bring about gastric or duodenal changes in subjects constitutionally predisposed to them That is a task for the psychologist and the applied physiologist to tackle together What more concerns the bulk of us is the bearing of these views on treatment Presumably it is beyond our power to change the psychological make up that characterises the ulcer patient All we can do is to protect him as far as possible from financial anxiety, increased responsibilities, and the worries of illness in his family To do that completely would need a perfect communist state, and would take all the zest out of his life How the ambitious, energetic ulcer bearer must inwardly resent this teaching! Or if he accepts it, his disability must be as galling to him as a withered leg, and he must be as sensitive about comment on it as a man with a gross physical deformity Is there no alternative or compromise? Is there no way by which the ulcer patient may learn to face most, if not all, the stresses of an active life with impunity? To appreciate and accept the relation between disturbing events and activity of his ulcer is clearly the first step, and a most important one It will point the way to a judicious use of rest and relaxation, as well as of diet, by the individual patient It will lead him to a more intelligent management of himself, and save him from a blind and often unavailing faith in alkaline powders, the avoidance of meat new fangled injections, or surgical operations

EDUCATION UNDER DIFFICULTIES

In modern war capacity for leadership and the offensive spirit are not enough; the trained intelligence is now every bit as valuable as in civil life. We are glad to read in a War Office pronouncement that "potential officer material" will not be sought in the first instance from boys leaving secondary schools at 18 or 19. Training will begin with the age-group 20–26, followed by that of 26–31. The younger men are urged to continue their avocations, to refrain from trying to enter the services, and to keep themselves fit. The authorities should recognise, too, that teaching requires the retention of the best teachers, and many of these are young men whose urge to serve in the forces should be treated with the same wisdom as that of their pupils. In one respect the problem of medical education is straightforward. Large drafts of medical men have already been provided for the defence services, and many more have been removed from ordinary practice to serve whole-time in emergency hospitals. The demand for doctors must therefore continue to be large, and moreover the mobilisation of the young men will do little to lessen the work of general practitioners and the public health services, for it has always been the women and children and the elderly who have made the greatest demands on them. The need for new licencees will then be urgent, and from the beginning of war preparations the Government have wisely recognised that those who are well launched on their medical studies must be conserved, and while university undergraduates have now been warned that they may be called up at the age of 20, medical students will remain immune.

The medical schools must be protected from disorganisation as far as possible. Many of their staff had territorial and reserve commitments and have already gone, and their replacement is not going to be easy. The position is further complicated by the extensive readjustment that has been necessary in hospital accommodation. Fortunately war came in the vacation, and there has been time for arrangements to be made, but even so modifications in the medical curriculum are likely to be unavoidable. Where senior students are attached to base hospitals near the danger areas the difficulties of lodging and transport and hospital staffing will encourage the practice of residential clerkships and dresserships which the General Medical Council has advocated. This return to a controlled form of apprenticeship in medical education will be a gain. In the provincial schools, which are to receive students from more dangerous places, the teaching hospitals have lost many of their available beds and clinical teaching will have to be spread over groups of hospitals, including those controlled by the local authorities, to a greater extent than formerly. The breaking of fresh ground may turn out to be as desirable in medical teaching as in farming. Students drafted to the big municipal hospitals are finding an unexpected wealth of clinical material, and those attached to mental hospitals are gaining an experience that has never before come the way of undergraduates. Systematic instruction under these conditions will require much ingenuity, but fortunately the plans outlined on page 757 suggest that this is forthcoming. It is unfortunate that the peculiar status of the General Medical Council in relation to medical education seems to preclude its taking the initiative and offering the central guidance which would now be so useful. But the Minister of Health was himself at one of the medical schools and should therefore take a professional view of their interests.

NEPHRITIS AND NEPHROSIS

TWENTY-FIVE years have elapsed since VOLHARD and FAHR published their famous monograph, Die Brightsche Nierenkrankheit, in which nephrosis was clearly separated from glomerulonephritis. Following MÜLLER, nephrosis was defined as an affection of the kidneys in which degeneration was predominant and inflammation played a secondary part. The group included the symptomatic nephroses, complicating conditions such as amyloid disease and eclampsia, as well as the so-called simple nephrosis of Bright's disease, which later came to be known as lipoid nephrosis. This distinction was widely accepted during the last decade, controversy centering round the primary cause of the disorder, whether metabolic or renal, and the relationship of nephrosis to glomerulonephritis. It was recognised that a group of cases exists in which the clinical picture is initially that of nephrosis—massive œdema, albuminuria and oliguria, without hypertension, renal failure or hæmaturia—and yet later on hypertension and nitrogen retention may develop. Such cases seemed to form a link between glomerulonephritis and nephrosis and have been called nephrotic nephritis or nephritis with a nephrotic *Einschlag*—a term not readily translated or defined.

The validity of VOLHARD and FAHR'S separation has now been questioned. BELL[1] claims that chronic proliferative glomerulonephritis may sometimes reproduce completely the clinical syndrome which we have been accustomed to call lipoid nephrosis. Nephrosis, he thinks, is a form of glomerulonephritis in which the glomerular capillaries remain open and allow the plasma proteins to escape into the urine. Following FAHR, he regards thickening of the basement membranes of the glomerular capillaries as characteristic of this group, which he terms rather unfortunately the membranous type of glomerulitis. The acceptance of this change as a diagnostic feature has, however, led him to include cases which, on clinical grounds alone, would not be admitted by most authorities as examples of nephrosis. Moreover, in 25 cases diagnosed clinically as lipoid nephrosis, there were 6 which showed no glomerular changes even though the history was as long as sixteen months. Arguing in a circle, BELL maintains that the capillaries must have suffered damage because of their permeability to plasma proteins, and their failure to respond by thickening was connected with the

1. Bell, E. T., *Amer. J. Path.* 1938, 14, 691.

youth of the patients. Yet in 2 other of his cases, aged twelve and thirteen years, the thickening was striking. Obviously this glomerular capillary change is not as significant as BELL would have us believe. In this country, DUNN[1] has adopted a somewhat similar view. He too has stressed the abnormal permanent patency of the glomerular capillaries in nephrosis and has suggested that it was perhaps the result of previous inflammation. He has also observed abnormal thickening of the basement membranes in certain of his cases.

While the tide is now running against the conception of nephrosis as an entity distinct from nephritis, advocates for the opposite view are not lacking. PANTIN,[2] working at the nephritis clinic at Guy's Hospital, has made a statistical study of glomerular size in nephritis, nephrosis and the normal kidney and has found that glomerular enlargement is a constant feature in glomerulonephritis, whereas in nephrosis there is no measurable difference from the normal. His 6 cases of nephrosis showed in fact no glomerular changes at all. Confirmation of his observations in a larger series would help to keep the controversy alive.

WHAT IS AN URGENT CASE?

DURING the past three weeks many people have been asking themselves the meaning of the word "urgent," for our hospitals have been dealing only with urgent cases. It soon became clear that the word had to be extended beyond such familiar emergencies as intestinal obstruction and compound fractures. There were, for instance, cases of ear disease to be observed for a time before making a decision for or against operation. Those working in the London voluntary hospitals have been thinking over this matter since the emergency bed service of the King's Fund was introduced. Under this scheme the hospitals agreed to take any case sent up as an emergency by any doctor without selection, in the way that the municipal hospitals have always done. The most striking thing about this service has been the number of times when the emergency has proved to be a false alarm, and the patient has been well enough to return home next day or the day after. This does not mean that the trouble was not urgent in the first place. The urgency must be assessed by the considerations in the mind of the doctor at the moment he sees the patient, and not on the report of the case when the patient is well again. Students have been taught for years that in certain conditions immediate transfer to hospital is necessary if a life is to be saved. We cannot criticise the man outside for failing to send in the acute appendix which might have been saved, and then turn round on him and grumble because he sends in all those other patients whose symptoms were identical at the moment he saw them but who were well next day, and back at work the day after.

But here is the difficulty. When a patient has been admitted as an emergency it is impossible to send him out next day, and difficult to do so on the day after. He may have to be kept in for a week to be investigated so as to exclude possible chronic disease, of which the acute symptoms were merely an exacerbation, and when a patient has been kept in hospital for a week we cannot think of sending him back to work for another week. The results are a strain on hospital beds, a large call on national health insurance funds, and, perhaps most important of all, the manufacture of invalidism in many of that great group of patients in whom no organic disease is discovered. Perhaps good may come from the present stringency of beds by giving courage to hospital doctors to send out these cases in forty-eight hours. That they should be admitted we can hardly doubt, when it is remembered that the hospital medical officer is to the doctor outside what the latter is to the patient. It is well known that of a hundred emergency calls the anxiety of the relatives is the only reason for ninety-eight. In the ninety-ninth the doctor saves a life, and in the hundredth—usually the one to which he does not go—the patient dies, but would have died anyhow. The public have been taught that certain symptoms are signs of grave disease and that they must call in their doctor at once. Through its insurance committees the nation demands that the family doctor should go out at all times and in all weathers to see such patients. It would be most unjust to deprive him of the power to deal with such cases if he finds the patients' fears may be justified. The criterion of urgency in the G.P.-patient relationship is the anxiety of the patient and his relatives, while in the hospital-G.P. relationship it is the suspicion rather than the certainty of serious disease.

But there is another way in which the relativity of the word urgent is being demonstrated. As our patients return to the outpatient departments which are now opening again we have to ask ourselves to whom shall precedence in admission be given? This will need careful consideration. It would probably do no harm, with the coming of the winter, if all tonsillectomies in children were deferred until the spring. On the other hand, the ingrowing toenails, the hammer toes, and other minor maladies of the feet that form the most important work, from the national standpoint, of our orthopædic departments, become increasingly urgent as the limitation of transport compels the population to resort to its legs. Precedence must also be given to those cases of malignant disease in which there is a hope of cure. Here also our knowledge may be extended if clinicians have to distinguish more carefully between cases in which hope really exists and those in which operative surgery is but a placebo and radiotherapy a mask of black magic. Nor must it be assumed that delay is a misfortune. A wait for three weeks will not have materially affected those growths which are curable, the rapid development of others should not be interpreted as a missed opportunity, for it may all too often be evidence that the growth was from the first incurable with our present powers.

ANNOTATIONS

CHEMOTHERAPY IN ANTHRAX

Two papers on experimental anthrax in our last issue (pp 681 and 685) open another chapter in chemotherapy with the sulphonamide group. Both workers used mice for their experiments and injected strains of *B anthracis* of known virulence Dr. May shows that M. & B. 693, and to a less extent sulphanilamide and sulphone, prolonged life in the animals infected with fully virulent capsulated non-sporing anthrax bacilli, although these drugs did not prevent ultimate death. Dr Cruickshank has obtained similar results, but when very large doses of M & B. 693 were given (60 mg. by the mouth plus 40 mg. subcutem) daily, he found that a considerable proportion—30–37 per cent according to the size of the infecting dose—survived, while no organisms could be recovered from the tissues As the author notes, these mouse doses multiplied weight for weight would imply an enormous dose of M. & B 693 for man. Dr Cruickshank concludes by speculating whether this drug would enhance the effect of a specific antiserum Dr. May answers this question with experiments which show that there was no apparent increase in the protective action of an anti-anthrax rabbit serum when used in combination with M & B. 693 The dose of the drug administered was, however, considerably smaller than that used by Dr Cruickshank in his survival experiments. Much of the importance of both these records lies in the biological character of the anthrax organism Like the pneumococcus, against infections with which M & B 693 has been so successful, *B. anthracis* possesses a well-defined capsule Numerous workers cited by Topley and Wilson [1] have, however, shown that the capsule is chemically different in the two organisms In the case of the anthrax bacillus a protein-like substance has been obtained from the capsule and a polysaccharide from the body, whereas in the pneumococcus the main part of the polysaccharide fraction is in the capsule Although its precise nature varies with the different types of pneumococcus, this polysaccharide portion is probably fully antigenic; but the polysaccharide fraction in the body of the anthrax bacillus is not, and the antigenic properties reside in the protein fraction of the capsule. It may be recalled here that a fraction has been extracted (Stamp [2]) from a hæmolytic streptococcus with dilute ammonia which is capable of antagonising the bacteriostatic action of both sulphanilamide and M. & B 693, and that this fraction is free from protein and consists of a mixture of substances of relatively low molecular weight, including free amino-acids. Obviously the chemical composition of the bacterial cell is of paramount importance in chemotherapy, whether of pneumococcal or other infections The results of Dr. May and Dr. Cruickshank in the case of anthrax are in harmony with this view and offer a hope of success in a disease which is usually fatal both in man and in susceptible animals

THE HISTOLOGY OF THE LUNG

FURTHER information about the structure of lung tissue is provided by Engel and Newns.[3] They examined microscopically the lungs of 196 children between the ages of six weeks and twelve years, using several methods of differential staining to define exactly the amount and distribution of smooth muscle in the lung parenchyma Serial sections, from 10 to 35 μ, were cut from paraffin-embedded material and camera-lucida drawings were made The structural details were followed in 27 selected cases by spreading out the drawings on a large table, marking particular groups of muscles and following the marked groups from drawing to drawing Certain interesting results justified the labour entailed.

Contrary to the accepted description,[4] no muscle-fibres could be found in the visceral pleura or in the interstitial tissue of the normal child's lung The terminal bronchioles and the mouths of the air-spaces all contained slender muscle-fibre bundles, Single fibres occurred up to the periphery of the ductules In a number of lungs where an antemortem solidifying process had been present (chronic congestion, chronic pneumonitis or miliary tuberculosis), the lymphatics of the interstitial substance were surrounded by muscle bundles and occasional isolated strands were seen radiating from them. All the muscle groups of the air-spaces were larger and more prominent, the change being at the expense of the elastic tissue Engel and Newns feel that, as Maxwell Ellis has shown for the larger bronchi [5] and Engel for the bronchioles,[6] the muscle of the interstitial and acinar tissue has a tonic-supporting function. Where the lung remains solid for some time the extra demands made on the muscle to preserve the patency of the air-spaces and lymphatics result in its hypertrophy This hypertrophy can be extreme—as in one of their cases and in the one described by Baltisberger—and this excessive reaction is perhaps attributable to a congenital predisposition. The same predisposition is possibly a factor in the causation of asthma

REGULAR OR ROUTINE EXAMINATIONS FOR CANCER?

As soon as it was realised that cancer is a local rather than a constitutional disease the need for early diagnosis, before metastasis occurs, became apparent But when a few years ago proposals were made for an educational campaign designed to lead the public to undergo regular examination for cancer, two objections at once became obvious In the first place it was useless to enlist the coöperation of the public until there were adequate facilities for diagnosis, and for immediate treatment. In certain centres these opportunities are to be found, but no nation-wide appeal could reasonably be made until all cancer-bearing patients already presenting themselves could be dealt with It was to remedy this deficiency that the Cancer Act was recently introduced and passed. One may suppose that if peaceful conditions had continued the Government would soon have been in a position to urge all adults over a certain age to submit to regular examination for malignant disease The fate of this part of the programme will depend on peace, prosperity and the reconstructed health plan of the nation when this war is over.

The second objection raised to a campaign for early diagnosis is that the public would not coöperate; and this would have been much harder to counter. It is true enough that, as the Minister of Health said in introducing the Cancer Bill, public opinion has changed in regard to tuberculosis, and may now do so towards cancer But the individual's objection to

regular medical examination is more profound. Robust people hate to be reminded unnecessarily of the ills of the body, hence they have an inertia towards physical probing. Even the injunction to visit the dentist every six months is ordinarily ignored—chiefly because it is too much of a bother. One doubts therefore whether even in a regimented population success would attend a scheme such as was introduced this year in Danzig by which women over 30 and men over 45 were enabled to undergo an annual examination for cancer free of cost to themselves.[1] A large number of people in almost any population will pay one visit of this nature to the doctor, and all the hypochondriacs will pay them regularly, but will they keep it up in year after year of good health? On the other hand, figures such as those published by Löwen[2] and by Mikulicz-Radecki[3] from Königsberg carry conviction about the need for *routine* examination for cancer of all patients seen. The method they extol and call "Reihenuntersuchung" is no more than every medical student is taught. The word itself implies a series of examinations, and so far as the early diagnosis of cancer is concerned the series must be made on the same patient. No data are given by either author of repeated examinations of the same people. One or two visits only to the doctor some time after the age of 30 will not achieve the saving of life that an early diagnosis campaign foresees.

ALL ABOUT DR. MAVOR

After tumbling in the hay with Dr. Gogarty we may now take a roll in the heather with Mr. Bridie (once Dr. Mavor), who has described for us the doctor's way of living for the past fifty years.[1] He has dashed off the biography while waiting for an interview with St. Peter, and between the chapters we listen with respect to his encounters with Mrs. Aphra Behn, Barrie, Colley Cibber, and other stimulating company who drop in to offer him advice and criticism. (With bated breath we hear him address Marlowe as a "bombastic old blatherskite.") Dr. Mavor was a Lowland Scot who was educated at Glasgow Academy and studied medicine in a leisurely fashion at Glasgow University. He had a theory—which he proved at the fifth attempt—that the whole of anatomy could be learned in a fortnight. This left him time to help edit the university magazine and to go camping with his cronies in Arran, where "one surrounded oneself with every conceivable discomfort and then drank bottled beer to forget them." He lived through a hectic rectorial election, when he and the present Minister of Health evolved a song (in Welsh) in support of Mr. Lloyd George, which may have been one of the reasons why Lord Curzon was elected. After qualifying young Mavor had only time for a short attack of house-man's head before he was overwhelmed by the last war. He served in France with the R.A.M.C., and later he was sent to Mesopotamia. Mr. Bridie does not believe in pandering to his readers. Dr. Mavor's life in the East was described in a book published in 1926 and if the reader is now unable to obtain a copy of that book, Mr. Bridie is unmoved and refuses to repeat the tale. So we soon return to Glasgow where Mavor, after he had been demobilised set up in general practice. He also spent some time helping at a psychotherapeutic clinic for shell-shocked veterans where he decided that to build up a personality is a job only to be undertaken by Socrates, Christ and Confucius working in the closest cooperation. In 1923 with a bank balance of £13 4s. 1d., Dr. Mavor married, and soon he was appointed professor of medicine at the Anderson College of Medicine. But already his metamorphosis into James Bridie had begun. He was writing plays for the Scottish National Players, and by way of Birmingham and Malvern he had soon reached London and the West End stage.

Mr. Bridie says that a Scotsman is a good biographer but a bad autobiographist, certainly he is to be congratulated on his study of Dr. Mavor.

ACTION OF T.N.T. ON THE BLOOD

With the outbreak of another European war closer attention must again be paid to poisoning by trinitrotoluene, which was first put forward as an explosive in 1891. During the war of 1914–18 Livingstone-Learmonth and Cunningham[1] described the effects of T.N.T. on women working in the filling sheds of munition factories, where the work necessitated intimate handling of the powder. They classified the symptoms into two groups—*irritation* and *intoxication*. The latter included the following referable to the circulatory system: faintness, giddiness, hot and cold flushes, pallor, slight cyanosis, occasional palpitations, swelling of hands and feet, and occasional ecchymoses. A special susceptibility was also noted in certain women—namely, those "inclined to anæmia," those with previous gastric, hepatic, throat, or chest trouble, those who sweated profusely or were unclean in person, alcoholics, and those with lowered vitality due to over-fatigue or malnutrition.

In an official communication from the Ministry of Munitions,[2] the blood changes in T.N.T. poisoning were described thus: they "appear to be the same kind as, though less in degree than, those mentioned already for D.N.B." (dinitrobenzene). "The presence of methæmoglobin may be demonstrated commonly in the blood of workers, though cyanosis and breathlessness are much less evident than in the case of D.N.B. poisoning." The changes in D.N.B. were referred to in the following terms:

"As in nitrite poisoning, there is a conversion of oxyhæmoglobin to the more highly oxidised form methæmoglobin. Beyond this there may be, when the poisoning is more severe, hæmolysis, with degeneration of the corpuscles and escape of methæmoglobin into the plasma. In severe cases evidence will be found not only of destruction of red corpuscles but also of activity in the blood-forming organs, nucleated red corpuscles may be found in severe cases, with evidence of imperfectly developed corpuscles, as shown by the occurrence of basophile granulations, polychromasia, and variations in shape and size. Lymphocytosis may also occur."

This description of the blood changes in D.N.B. poisoning appears to be based on Malden's report,[3] in which he said that the red cells were considerably reduced in number, varied in size and shape, and constantly showed basophil granulation, nucleated red cells were occasionally present, hæmoglobin was decreased, the colour index was normal, the white cells showed a total increase with a relative decrease of polymorphs, and the number of eosinophils was sometimes, and of mast cells more often, relatively and absolutely increased. In commenting on the note sent to us by the Ministry of Munitions we remarked that "the points of analogy between dinitrobenzene poisoning and trinitrotoluene poisoning are rendered additionally interesting by the resemblance of both

conditions to chloroform and to 'dope' poisoning" (due to tetrachlorethane).[4]

In 1921 a report to the Medical Research Council[5] showed that among the clinical features observed in T.N.T. poisoning was anæmia; which in its more severe forms was aplastic. In experimental work on animals it was possible in only two animals to induce changes similar to the aplastic anæmia and toxic jaundice as seen in man. These changes were not due to direct hæmolysis by T.N.T. The extreme reduction of the blood-forming marrow was the chief effect of the poison in the cases of aplastic anæmia. The cell-count was thus that of a rapid progressive primary anæmia with a high colour-index. Further details of the blood changes are now given by Bizzarri,[6] who has found in experiments on guineapigs that effects are produced on red cells, white cells, and platelets, some by the toluene group, and others by the NO_2 group of trinitrotoluene. The red cells are increased by the NO_2 group, and one of several types of anisocytosis, either macrocytic or microcytic, is constantly produced by the toluene fraction. A slight poikilocytosis may also be found. There is a leucopenia, due to toluene, with slight eosinophilia and a relative monocytosis, and a shift of the Arneth count to the right. The number of the platelets is slightly decreased by the effect of toluene.

In his latest annual report the chief inspector of factories records that last year there were five cases of "aniline poisoning" and one case of toxic jaundice due to contact with T.N.T. in a shell-filling factory.[7]

THE PSYCHO-BIOLOGICAL APPROACH TO PSYCHIATRY

BEFORE astro-physics and biochemistry had put understanding of the external world out of the reach of the ordinary man, the search for the nature of reality as revealed by science was open to anyone who cared to pursue it. It was remarkable that each new step which threw light on that reality evoked a storm of resentment. So conservative and so anxious for the security of the established order was man. But nowadays things have changed. If tomorrow the fundamental nature of the electron were discovered, or the dynamic quality of living protoplasm were revealed, it is doubtful that it would cause much stir. But this does not apply to psychology, and it is doubtful if it ever will. The investigation of our internal environment is so bound up with our own emotional conflicts that we shall always feel a bias towards this science. With the new dynamic view of the mind came a wealth of data and theory which split up psychiatrists into the various schools of today. In this country the general attitude towards dynamic psychiatry has been that of the fence-sitter—recently advocated in these columns.[8] In America, where there is a much greater tendency to accept broad generalisations, some measure of accord has been reached.

Followers of the psycho-biological school of Adolph Meyer and Diethelm will recognise in Dr Arthur Noyes's book on clinical psychiatry[9] the same fundamental theme which has attracted so much attention in recent years. The pure but sterile atmosphere of Kraepelinian description of clinical types has been reinforced by a vital psychology which envisages man as a psycho-physical unit striving to keep equilibrium in potentially hostile internal and external environments. Normal behaviour and psychotic symptoms are explicable as phenomena of this equilibrating process. Psychic energy is considered to be intimately bound up with physical processes, and it is postulated that there is "presumably a reciprocal relation between psychic energy and nerve energy, the physico-chemical basis of the latter existing in the Nissl bodies of nerve cells." The concept of the libido is given a much wider meaning than it is by Freud or Jung. Noyes regards it as "that aspect of biological energy which continues the race pattern and motivates the psycho-biological drives of the individual." The instincts derive their energy from this common source. Most of the better-known Freudian mechanisms are described and accepted, but it is a relief to discover that conscious control has still a large part to play in behaviour and in the promotion of normal mental health.

When considering disease processes, Dr Noyes constantly reminds us of the dynamic unity of the individual and bids us treat the total organism. A stimulating though perhaps naïve example is given in the chapter on paranoid psychoses. It is known that death in such patients is more often due to degenerative circulatory disease than in the other biogenetic psychoses. The author states—"the antecedent hypertension and cardiac hypertrophy followed by subsequent degeneration and failure when the demands of the cardio-vascular system become too great represent a compensatory somatosis associated with a compensatory psychosis."

This is probably the only modern text-book which gives any detailed account of insulin and cardiazol shock therapies. Much of the best research of the last five years is included. A new chapter has been added on psychiatry and general medicine, which, while perhaps out of place in a book for psychiatrists, contains material which any surgeon or general physician will find valuable. The author concludes with some words of Fritz Mohr—"there is no such thing as a purely psychic illness or a purely physical one, but only a living event taking place in a living organism which is itself alive only by virtue of the fact that in it psychic and somatic are united in unity."

LEISHMANIASIS IN EUROPE

CONCLUSIVE evidence, including the culture of *Leishmania tropica*, is brought forward by Poggi and Monti[10] that, in an extensive area comprising about a dozen townlands in the valley of the river Conca, which lies in the Italian provinces of Forlì and Pesaro on the Adriatic coast, many cases hitherto diagnosed as lupus are in reality oriental sore. No mention is made of the species of sandfly concerned in this district. Although *Phlebotomus papatasii* had hitherto been held responsible for oriental sore in Europe, Vanni[11] inculpated *P. macedonicus* (Adler and Theodor 1931) alias *P. perfiliewi* (Parrot 1930)[12] in one case in Abruzzi, and a typical oriental sore was produced in a rat by inoculation with the products of trituration of two thousand specimens of *P. perfiliewi* caught locally.[13]

Marseilles from 1923 to 1938, averaged 6–10 cases yearly, reaching a maximum of 24 in 1932, and that the incidence of canine leishmaniasis in the same area was closely comparable with the human as regards both geographical distribution and seasonal variation This appears to confirm the hypothesis that Mediterranean kala azar is a canine disease only occasionally communicated to man Since it was not clear that the disease was conveyed by sandflies or by fleas, it is suggested that the carrier is a tick, a theory which is supported by the fact that the disease is commoner among watchdogs and sporting dogs of suburban and country districts than among canine pets in towns

DISTANCE FACTOR IN GAS WARFARE

THE extent to which war gas will travel along the ground in dangerous concentrations is naturally an important question, not only for combatant troops but also for auxiliary services Wind currents will break up and dilute vapour and the lighter a gas is, the more quickly is it dispersed Denser and heavier gases may be carried down wind a long way and distributed over a wide area before they lose their virulence Figures based on theory are apt to be falsified Prof Gullert[1] of Berlin states that phosgene will not rise higher than about fifty metres but will spread at an angle of over 30° He gives a table which shows that a concentration of 1 4 per cent at the site of release may have thinned at three thousand metres to 0·004 per cent In favourable (or perhaps unfavourable) circumstances phosgene may be effective more than twenty kilometres away and detectable up to thirty kilometres The phosgene which escaped by accident at Hamburg in May, 1928, caused 130 casualties between two and seven kilometres away and was detected at fourteen kilometres If the air is still and humid, heavy insoluble gases may retain a high concentration at relatively long distances In 1930 an escape of an industrial gas (fluorine) filled a part of the Meuse valley over an area twenty five kilometres long and one or two kilometres wide, and caused 63 deaths in a single day[2] War gas also hangs about obstinately in woods Obviously it is impossible for troops anywhere near the line to feel quite safe Gas is, indeed a clumsy weapon, and may be abandoned on grounds of pure expediency

POLIOMYELITIS VIRUS IN FÆCES AND DRINKING-WATER

LAST year Trask, Vignec and Paul pointed out that when a filter (Chamberland or Berkefeld) is used in attempts to isolate poliomyelitis virus from fæces the concentration of the virus is likely to be so low that it may not infect animals into which it is injected, They suggested that filtration can be dispensed with when the stools are treated with volatile antiseptics such as ether or acetone Having adopted this suggestion Kling, Olin Magnusson, and Gard[3] report the case of a 7 year old boy who developed non-paralytic poliomyelitis in the autumn of 1938 After his recovery, his stools were treated as prescribed by Trask and his colleagues and a monkey (*Macacus cynomolgus*) was given an injection into the peritoneal cavity and another into one of its sciatic nerves Paralyses ensued, and autopsy revealed the changes characteristic of experimental poliomyelitis A *Macacus rhesus* was successfully inoculated with material from the first monkey, and the disease was transmitted from the second to a third monkey Subsequent tests with the stools of the same child suggested that their content of the virus of poliomyelitis was gradually waning, for when a monkey was inoculated 31 days after the first inoculation only an abortive form of poliomyelitis developed, and the result of a further test 120 days after the commencement of the illness was wholly negative

These investigations were brought to the attention of the French Academy of Medicine on June 13 of this year, and on July 18, before the same forum, Lépine, Sédallian, and Sautter[4] described related findings They said that on Nov 8, 1938, a man aged 28, living in the neighbourhood of Lyons, was admitted to hospital moribund from an exclusively bulbar form of acute anterior poliomyelitis It transpired that his two children had been feverish about the time that he had fallen ill, but had recovered without developing paralyses The stools of one of these children, treated in the manner described by Trask, Vignec, and Paul, yielded a fluid whose injection into a monkey (*M rhesus*) gave rise to typical experimental poliomyelitis About a month later, the child's stools were again tested against a monkey (*M cynomolgus*), which in its turn developed poliomyelitis with paraplegia, the post mortem changes being typical of experimental poliomyelitis When the stools were tested once more, about four months after the child first fell ill, the inoculated monkey developed only a transitory paralysis, followed by complete recovery About a month later the same monkey was found to be resistant to an intravenous injection of poliomyelitis virus It thus seems that the first inoculation of this monkey with material taken from the child's stools had made it immune to experimental poliomyelitis The blood of the same child also seems to have acquired defensive properties against poliomyelitis, for when the child's serum was mixed with a laboratory poliomyelitis virus, the monkey inoculated with the mixture remained well, whereas a control monkey inoculated with the same virus, to which no serum had been added, became paralysed and died

The latest observations on similar lines have been made at the Swedish State Bacteriological Laboratory under the direction of Professor Kling, who has been paying special attention to drinking-water as a possible source of poliomyelitis Numerous samples of water taken from homesteads and districts invaded by poliomyelitis have been tested and, in 1 out of 26 samples examined, what appears to be the virus of poliomyelitis has been found The sample was taken from a homestead in which a case of poliomyelitis had been diagnosed the day before, and on its effect on monkeys the virus obtained has so far conformed to the standards by which the virus of poliomyelitis is at present identified Nevertheless we understand that Professor Kling is as yet reluctant to commit himself to anything more than a provisional claim that his virus is identical with that of poliomyelitis of which there are known to be several serologically different strains It will be interesting to see his report to be published in the medical press in the near future

ÆTIOLOGY AND TREATMENT OF OSTEO-ARTHRITIS

By T. T. Stamm, M B Lond., F R C S

ASSISTANT ORTHOPÆDIC SURGEON TO GUY'S HOSPITAL; ASSISTANT SURGEON TO THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, LONDON

For many years confusion has existed in the minds of medical men about the significance of the articular changes called "osteo-arthritis" The relationship between these changes and such conditions as rheumatoid arthritis is often misunderstood. Although in such standard textbooks as Taylor's and Osler's the importance of trauma as an ætiological factor is emphasised in relation to the monarticular forms, no reason is given for these changes occurring in a polyarticular form or for their appearance in the later stages of rheumatoid arthritis Although stress is usually laid on such ætiological factors as infection, metabolic disturbances, and exposure to cold and damp, again no explanation is suggested why in some cases they produce a degenerative type of arthritis and in others proliferative or osteo-arthritic changes; nor is any suggestion made of a possible mechanism by which these changes could be produced

This confusion and uncertainty is unfortunate from the point of view of accurate diagnosis and for a clear conception of the forces at work in any particular case, but doubly unfortunate from the point of view of treatment; for, unless we have some conception of how a disease is produced, treatment must remain purely empirical.

In the Royal National Orthopædic Hospital and in the orthopædic department at Guy's Hospital I have been able to study many cases exhibiting the signs that we regard as characteristic of osteo-arthritis—namely, degeneration and wearing away of the cartilage in the central areas of the articular surfaces and eburnation of the underlying bone, associated with hypertrophy and overgrowth at the edges of the joint and the formation of osteophytes, and in the later stages hypertrophic changes in the adjacent parts of the synovial membrane, with the formation of adhesions and villous projections As a result I have come to the following conclusions. (1) osteo-arthritis does not develop primarily in a joint which is otherwise normal; (2) it only develops in joints already the seat of one of the various forms of arthritis or in joints whose physical conditions have been altered by trauma, usually of one of the articulating bones concerned; and (3) it is a truly mechanical arthritis, even when it is polyarticular.

Ætiology

Excessive wear takes place in the moving parts of any machine when they are subjected to abnormal stresses and strains through alteration in the physical conditions under which they work. This must apply equally to living joints; but, since living tissues always react in some way to altered physical conditions the complete clinical picture of a living joint which is the seat of excessive wear shows changes which are the direct result of pure mechanical wear, plus changes resulting from the reaction of the tissues of the joint.

I intend to show that this admittedly theoretical picture conforms exactly with the condition called "osteo-arthritis" and to suggest that osteo-arthritic changes in a joint are always and only of mechanical origin. If this view is accepted, osteo-arthritis may be defined as the sum of the changes in a joint where excessive wear is taking place as a result of some alteration in its physical condition. The acceptance of this hypothesis leads to the clarification of some of the confusion surrounding the classification of the various forms of chronic arthritis, for nearly all types of chronic arthritis must eventually alter the physical conditions of the joint and tend to produce excessive wear and tear. In their later stages all forms of chronic arthritis are therefore liable to show changes characteristic of osteo-arthritis, but such changes are a consequence of the arthritis and not a part of it, and they must be discounted if a clear picture of the particular form of arthritis is to be obtained

What then are the changes which may theoretically be expected to take place when a living joint is subjected to altered physical conditions? As stated above, they will consist in: (1) changes due to mechanical wear, such as would develop in an inanimate machine of similar structure; and (2) changes resulting from the reaction of the living tissues to the altered stresses and strains to which they are being subjected

CHANGES DUE TO MECHANICAL WEAR

Failure of lubrication is the main cause of excessive wear in any machine. This may be due either to a lack of proper lubricant or to breaking of the film of lubricant by excessive pressure between the opposing surfaces. When either of these conditions is present in a joint, the affected areas of the articular cartilage begin to wear away. As a rule the central areas of the cartilage receive most of the stress and must therefore show the most wear Proper lubrication in any joint can be assured only when the opposing surfaces are not exactly parallel, so that point or linear contact is made between them The slight V-shaped gap thus formed on either side of the line of contact causes the lubricating fluid to be compressed and forced between the opposing surfaces on movement. When wear takes place, the surfaces tend to be ground into too exact a fit, and so the joint tends to "seize" and to move in a series of jerks This might reasonably be expected to cause transverse ridges and cracks in the cartilage, such as develop on the surface of a road, and may be partly responsible for the "fibrillation" of the cartilage so commonly seen in degenerating joints

REACTION TO THE TISSUES

To deduce the probable reactions of the joint to abnormal stresses and strains it is necessary to bear in mind what happens in other tissues when similar forces are applied In nearly all tissues the reactions are similar: when excessive steady pressure is applied, the tissues atrophy; excessive intermittent pressure, on the other hand, tends to produce hypertrophy and overgrowth. When, however, the tissues are subject to a degree of pressure or stress which they are designed to withstand, no abnormal reaction takes place

The skin of the heel affords a simple example illustrating these points The normal even pressure of the body-weight on the skin of the under surface of the heel does not evoke any reaction, and the skin remains soft and supple. At the edges of the heel there is continuous hypertrophy and overgrowth of the skin, and so everyone has a ridge of thickened

skin round the edge of the heel, presumably due to the excessive intermittent pressure to which this strip of skin is subjected owing to the smaller area available. The same reaction takes place when one metatarsal head becomes depressed. The skin underneath it is subjected to excessive intermittent pressure, and a callosity constantly develops. When, on the other hand, excessive, but continuous pressure is applied, as in a badly fitting plaster, the skin and underlying tissues atrophy and a pressure sore develops.

Similar changes may be expected in joints under abnormal conditions of stress. Thus, in the central areas of the articular surfaces, where pressure is continuous and most likely to be excessive, atrophy and degeneration of the cartilage may be expected. This, together with the mechanical wear already mentioned, causes the cartilage to wear rapidly away until the underlying bone is exposed, and being exposed, may be expected to attempt to reproduce an ordinary cortical surface, which will be moulded to the shape of the opposing articular surface by the movements of the joint.

At the margins of the joint, however, the pressure or stress, though it may become excessive, is intermittent, and in this situation hypertrophy and overgrowth must be expected. Cartilage cannot hypertrophy to any great extent, but the marginal bone can do so and there will be overgrowth of bone round the margins of the joint, comparable to the thickened skin round the margin of the heel. The synovial membrane in this peripheral area will be liable to be nipped or rubbed by the adjacent bony overgrowths. In this way raw areas may be caused which will tend to stick together and produce adhesions in the joint, and hypertrophy of the synovial membrane may result from the irritation and produce villous projections.

The clinical picture produced must vary in different cases, for the reaction of the tissues depends to some extent on the state of their blood supply and therefore on the state of the general circulation. It is well recognised that the hyperæmia caused by certain types of inflammation leads to atrophy and absorption of bone, whereas sclerosis of bone is often found where there is a diminution of the local blood-supply. When, therefore, the local blood supply is deficient, hypertrophic reactions round the margins of the articular surfaces tend to occur, with sclerosis of the bone ends. On the other hand, when there is hyperæmia, the atrophic changes usually predominate, and bony outgrowths may not be formed.

The complete theoretical picture of a mechanical arthritis therefore consists of a joint in which the cartilage, especially in the central areas of the articular surfaces, is atrophied, split with transverse ridges or fibrillations, or even completely worn away. At the margins of the joint there is hypertrophy, with a rim of new bone formation. The synovial membrane in this area may also be hypertrophied and heaped up into ridges, and there may be multiple adhesions. In fact, all the typical changes of osteo-arthritis can be explained on an entirely mechanical basis, and at the same time this hypothesis can satisfactorily explain the pathological results in all types of cases in which the mechanical state of the joints has been altered no matter what the primary cause of this change has been.

CAUSES OF ALTERATION IN MECHANICAL STATE

Fracture into a joint.—When the line of fracture passes across an articular surface and perfect reduction is not effected, a ridge will be left, and the cartilage along this ridge will be subjected to excessive pressure, and so it will degenerate and wear away. Further, owing to the altered alignment of the articular surfaces, abnormal stresses are likely to fall on other parts of the joint, and so generalised changes may also develop. If the joint is stiff as a result of the original injury, these effects will be exaggerated, and degeneration will take place sooner than would otherwise be the case. This factor of free mobility in a joint is most important from the point of view of traumatic arthritis. The greater the natural mobility of a joint, the greater the possibility of "play" between the articular surfaces which enables it to take up unusual stresses and strains, and therefore the likelihood of damage being sustained to the articular surfaces by their being impacted together is considerably diminished. For this reason a flail joint in a paralysed limb is very rarely the seat of osteo-arthritis, whereas some joints—e.g., the hip joint—are much more liable to osteo-arthritis than others because a deep ball and socket construction does not allow play between the articular surfaces, and all unusual stresses and strains must be taken through them. In the shoulder joint, on the other hand, there is such free mobility and play between the articular surfaces that they can very rarely be impacted together, and osteo-arthritic changes are correspondingly rare.

Fractures outside joints.—When a fracture does not properly unite, the resultant angulation of the bone may throw a neighbouring joint out of alignment, so that it is subjected to shearing strains. For example, a fracture of the tibia producing lateral angulation of the lower end throws the ankle-joint out of the horizontal, and so the body-weight acts as a shearing strain on the upper surface of the talus. This will very soon cause excessive wear, and osteo-arthritis will supervene as a result of the altered mechanics of the joint.

Rheumatoid arthritis primarily affects only the capsule and synovial membrane of a joint, but as a result of the changes in these structures the joint becomes stiff and there is a lack of secretion of synovial fluid. Subsequent use of the joint will lead to excessive wear of the articular cartilage owing to improper lubrication, and the joint will at the same time be subjected to excessive stresses and strains owing to its stiffness. Eventually, therefore, the features of a mechanical arthritis will be added to those of rheumatoid arthritis. It is this factor which has caused so much of the confusion between rheumatoid arthritis and osteo-arthritis already mentioned. The changes typical of osteo-arthritis, which are so often seen in rheumatoid arthritis, are merely those of the mechanical arthritis which is an inevitable sequel to the damage caused to the joint by the rheumatoid disease.

In rheumatoid arthritis, however, the picture is altered by the presence of hyperæmia, which is such a constant feature of the active stage. Hyperæmia delays or prevents the onset of sclerosis of bone and so the degenerative changes predominate. When the articular cartilage has finally worn away, the hyperæmia may limit the condensation of the underlying bone, so that two soft cancellous bony surfaces come into contact. Since movement is restricted to a great extent by the stiffness of the joint actual bony union may then take place, particularly in joints, such as carpal or tarsal joints, where the normal range of movement is limited.

Later, when the disease becomes quiescent, the hyperæmia is replaced by anæmia, probably due in

part to the contraction of the fibrous tissue round the joint. At this stage sclerosis of the bone is likely to develop, with formation of osteophytes, provided that some degree of movement has been retained to provide the stimulus.

Gouty arthritis.—The effect of local anæmia in causing sclerosis of bone and a more proliferative type of arthritis explains the frequency with which these changes are found in elderly and in arterio-sclerotic patients. The products of disordered metabolism, such as are formed in gouty arthritis, damage the joints, and in some cases this is the primary cause of the subsequent osteo-arthritis. This form of arthritis also consists of two components: (1) the primary metabolic disorder with its local effects on the joint, and (2) the resulting mechanical arthritis. To these may be added a third factor—namely, anæmia of the tissues from the often associated arteriosclerosis. This factor tends to accelerate the deterioration of the joint and may increase the sclerosis of the ends of the bones.

Nutritional disturbances.—In many cases, especially in elderly subjects, no definite primary cause can be found for the osteo-arthritis. In such cases deterioration of the cartilage, which becomes soft and fibrillated, is usually the first change, and I suggest that this is probably due to deficient nutrition. In this sense such changes may reasonably be described as "trophic" and are probably a direct result of the often associated arteriosclerosis. Once such changes have taken place in the articular cartilage, the eventual onset of generalised osteo-arthritis becomes inevitable

(To be concluded)

GAS INJURIES TO THE EYES

THE damage to the eyes that may arise from high explosives and incendiary bombs will not differ essentially from that met with in peace-time practice, and its treatment can be based on established principles, but injuries due to gas are largely an unknown quantity.

Though the value of gas as a measure of offence in comparison with high explosives is open to doubt, and therefore the extent to which it will be used in this war remains to be seen, the possibility that it will later be employed to produce panic and disorganisation among civilians must be prepared for.

The experience gained in the last war, however, may not be applicable to this, not so much because new unknown gases may be used but because the methods of distribution of gases are now more effective.

Almost all gases used in chemical warfare cause some ocular discomfort and lacrimation, but the groups known as lacrimators and vesicants are of special significance. The lacrimators produce severe subjective symptoms, which are mainly ocular but also include burning sensations in the throat and pain and discomfort in the chest when patients are exposed to relatively high concentrations. The eye symptoms are outstanding—they consist of a stinging in the eyes, immediate and profuse lacrimation, and spasm of the eyelids, sometimes so severe that the victim is unable to open his eyes at all. These symptoms, though alarming, are transient, and within a few hours the whole condition subsides, leaving no permanent after-effects.

As against these dramatic and obvious effects of the lacrimators, the action of the vesicants is insidious This group comprises mustard gas and the allied Lewisite, the latter, though first prepared in 1917, has not as yet been used in war. When the eye is exposed to mustard gas there is a latent period whose duration depends on the concentration of the gas. In the last war it was, as a rule, six to eight hours, though sometimes it was as short as two hours, and it is absent when gas in its liquid form splashes directly into the eyes. After the latent period pain and a feeling of grittiness under the lids develop, followed by photophobia, blepharospasm and profuse lacrimation. The lids become œdematous and glued together. The conjunctiva, particularly in the interpalpebral area, is intensely engorged and swollen Where the cornea is involved, the photophobia and blepharospasm are more severe, and the patient may think himself blind because he cannot open his eyes. There is no purulent discharge unless secondary infection takes place In cases of corneal involvement the part of the cornea that is covered by the upper lid is usually unaffected. The exposed interpalpebral area loses its lustre, a turbid horizontal band is thus seen stretching across the clear cornea to become confluent with the affected interpalpebral conjunctiva. The pupil is contracted. Abrasion, ulceration and secondary infection may all occur, rendering the immediate prognosis more grave. Where there has been a direct splash with liquid gas intense lacrimation sets in within a few minutes; within half an hour there is great injection of the conjunctiva and within an hour progressive chemosis Infiltrating ulceration involving the cornea, conjunctiva and lids develops The corneal lesion is similar to that of any severe caustic burn, but the slowly progressive damage and delayed healing more resemble an X-ray burn

During the last war only about 10 per cent of gassed men developed corneal lesions—mostly transient—and it is said that only about 15 men in all were blinded by gas This figure is almost certainly an underestimate, if the cases of late keratitis, not recognised till several years after the war, are included. None the less, the figures do help us to place the risks of mustard gas to the eyes in their proper perspective, for protective measures against gas have developed considerably in the last twenty years.

TREATMENT

Fundamental difficulties arise in treatment Experimental works by Warthin and Weller[1] on various animals suggests that the action of gas is instantaneous. If drops of liquid mustard gas are put on both corneas of an animal, and one eye is at once thoroughly irrigated, the lesions in the two eyes on the following day are identical Histologically all the layers of the cornea are involved, and in severe cases the whole of the cornea is necrosed, exposing Bowman's membrane If these findings are applicable to man, the end-result will be determined almost entirely by the concentration of the gas reaching the eye, and treatment can only be directed to relieving symptoms and combating the cumulative action of the gas This lamentable view, which is generally accepted, is contested by Bonnefon,[2] who points out that horses were more affected than men by gas during the last war, and records the severe

1. Warthin, A. S., and Weller, C. V., Medical Aspects of Mustard Gas Poisoning, St. Louis, 1919.
2. Bonnefon, *Gaz. scien. méd. Bordeaux*, March 12, 1939, and *Siècle méd.* Sept. 1, 1939.

course of eye lesions in animals as the result of the absence of lacrimal secretion with its defensive mechanism As against the classical treatment—irrigation with some bland lotion such as sodium bicarbonate solution, instillation of castor oil or liquid paraffin, and atropine drops where necessary—Bonnefon advocates measures to increase the flow of tears and induce drainage from the conjunctiva and cornea by osmosis He regards oily drops as harmful because they absorb the gas and thus keep it pent up in the eye, ointments he condemns for the same reason and also because they impede the flow of tears by glueing the lids together He suggests irrigation for 10 minutes, two or three times a day, with a hypertonic lotion such as saturated solution of sodium sulphate 800 grammes, solution of glucose 200 g

One other method of treating severe corneal lesions may perhaps be found applicable Of late years Denig has proposed immediate mucous grafting of the cornea in severe caustic burns, the graft being taken from the mucosa of the lower lip The results are said to be gratifying, and this method may be worth trying out in exceptional cases

In all degrees of eye lesions from mustard gas two symptoms require special attention, as was urged by Sorsby at the Aberdeen meeting of the British Medical Association The blepharospasm induces a fear of blindness with a severe anxiety state By gently separating the lids the patient can be convinced of the groundlessness of fears The pain that patients experience has led to the suggestion that cocaine drops should be instilled, but most authorities agree that cocaine should be avoided owing to its devitalising effect on the corneal epithelium Substitutes such as Pantocaine and Larocaine have also been recommended,[3] and Dor[4] advocates 2 per cent dionin drops Where pain is severe, atropine is generally indicated because of the associated corneal lesion, and this should usually suffice

GENERAL POST

MOVEMENT OF THE MEDICAL SCHOOLS

DETAILS of the arrangements for the future of medical education in London and the provinces have now been worked out by most medical schools. In general, it may be said that preclinical teaching in London is to stop, the London students being transferred to various provincial universities The clinical teaching of the London schools, on the other hand, is to continue in the hospitals of the sector of each teaching hospital The provincial schools are staying where they are, though many of them will have to make changes in organisation to cope with the London evacuees In most cases these newcomers are bringing their own teachers with them, and the students will continue to take London examinations The arrangements for clinical teaching in hospital sectors vary as yet in completeness The most usual plan appears to be to dispatch those needing elementary clinical instruction to the base hospital, while the other students are divided into small groups that will move from hospital to hospital At certain hospitals usually those accommodating the sector pathological laboratories arrangements will be made for teaching practical pathology and as a rule one or two hospitals in each sector have adequate facilities for midwifery

Groups of students will be on duty at casualty clearing stations for short spells

The system will offer certain great advantages The amount of clinical material and the opportunities for practical experience will be enormously increased, and this should more than compensate for the dispersal of clinical teachers Many students will for the first time realise that municipal hospitals are not to be despised, and that there are many whole-time doctors in municipal service who can hold their own at the bedside with their voluntary-hospital colleagues In some of the smaller hospitals, general-practitioner members of the staff are already doing their share of teaching, and the students are learning at first hand that general practice is not the occupation of the second-rate doctor The position of the clinical students will be reviewed by the deans of the London hospitals towards the end of the year

The arrangements for the London medical schools will be reviewed by their deans towards the end of the year, at present they are as follows —

St Bartholomew's.—The preclinical anatomy and physiology will be carried on at Cambridge, while clinical studies will go on at St Bartholomew's casualty clearing station and the other hospitals in sector 3 Teaching in first year subjects has yet to be arranged

Charing Cross.—Preclinical students for Charing Cross Hospital normally attend King's College They will follow King's College to Glasgow University Clinical students will be distributed throughout the hospitals of sector 4 Teams of surgical dressers and blood-transfusion groups have been arranged Clinical beginners are likely to be posted to the base hospital and an interchange of students between the hospitals to vary clinical experience will probably be organised The address of the secretary of the Medical School is 81, St. Margaret's Road, Twickenham, Middlesex (Tel : Popesgrove 1226)

St George's.—Preclinical students who normally study at King's College will be transferred with that college Clinical students are dispersed throughout sector 7 About 25 are at Isleworth, 15 at Staines, 10 at Slough, and smaller numbers at various L C C hospitals

Guy's.—The preclinical students at Guy's will not go to Oxford as previously announced but to Sherwood Park, near Tunbridge Wells Students will be lodged in private houses converted into hostels Clinical students are distributed to the hospitals throughout sector 10

King's College Hospital.—The preclinical students at King's College will go to Glasgow University The clinical students have been distributed through the hospitals in sector 9

The London.—Preclinical students are to go to Cambridge They are being provided with board and lodging at St. Catherine's College, but their teaching arrangements are in the hands of their own professors and not the university staff Clinical students are distributed throughout the hospitals of sectors 1 and 2 Subject to the approval of the county borough councils concerned, teaching will be carried on in the municipal hospitals at Romford, Rochford, and Whipps Cross, and in many voluntary hospitals including Southend General, Queen Mary's at Stratford, and the King George V Hospital at Ilford In sector 2 there are 12 large L C C hospitals and also two important Middlesex county council hospitals A service of dressers at casualty hospitals in dangerous areas will be maintained and students will take turns for short spells on duty at these casualty hospitals Facilities for teaching obstetrics will probably be available at the Hackney and Mile End Hospitals of the L C C, at Oldchurch County Hospital, Romford, and at Brockett Hall which is being opened as an obstetric hospital for the county of Hertfordshire Courses in pathology will be organised at Billericay Hospital under Professor Bedson, pathologist to

3 Stallard, H B, *Lancet* Sept 2 1939 p 516
4 Dor quoted in *Pr méd* July 5 1939, p 1066

sector 1, and at Chase Farm P.A.I., Enfield, under Dr. Panton, pathologist to sector 2. The secretary of the medical school should be addressed c/o St Catherine's College, Cambridge, and the dean can usually be seen there on Sunday mornings at 11 A.M. Letters for the dean should go to the headquarters of sector 1, emergency hospital organisation, Essex County Hospital, Hermon Hill, Wanstead, London, E.11.

London Hospital Dental School.—The headquarters of this school will be established at Claybury Mental Hospital, Woodford Bridge, Essex. Subsidiary centres for clinical dental teaching will be opened at St. Margaret's Hospital, Epping, Haymeads Institution, Bishop's Stortford, St. Andrew's Hospital, Billericay, and probably also at Chelmsford P.A.I. and the Chase Farm. P.A.I.

St Mary's.—Preclinical students are to work at Manchester University. Clinical students will be distributed throughout the hospitals of sector 6.

Middlesex.—Preclinical students will be moved to the University of Bristol where they will continue under their own Middlesex teachers. Clinical students will be distributed throughout the hospitals of sector 5. Some will be at the Middlesex Hospital C.C.S. itself, others at the Mount Vernon Hospital, the Royal Bucks Hospital, Aylesbury, the Ministry of Health Emergency Hospital at Aylesbury, the Willesden General Hospital, and so on.

Royal Free.—Students working for the first medical examination are to go to St. Andrews University. Those working for the second M.B. are to go to Aberdeen University. Clinical students will work at the hospitals in sector 3, some continuing at the Royal Free C.C.S., while others will be at the base hospital at Arlesey in Bedfordshire.

St. Thomas's.—Preclinical students are to move to Oxford, while clinical students are to be distributed among the hospitals of sector 8.

University College.—The students of this college have been moved en masse to the University of Wales, Aberystwyth. The women preclinical medical students are, however, to go to Sheffield.

University College Hospital.—The clinical students are distributed through the hospitals of sector 4. Arrangements have already been made for clinical teaching at the West Herts Hospital, Hemel Hempstead, and at the Leavesden Hospital. A nucleus remain behind at University College C.C.S.

Westminster.—Preclinical students at King's College will follow that college to Glasgow. Clinical students will be distributed throughout the hospitals of sector 7.

University of London.—The administrative offices of the university are now located at the Royal Holloway College, Englefield Green.

British Postgraduate Medical School.—Postgraduate teaching has practically ceased, but 27 undergraduate students are attached to the Hammersmith Hospital, in connexion with the E.M.S. scheme. These are receiving clinical instruction in medicine, surgery, midwifery and pathology, on the 300 civil sick occupying some of the 700 beds of the hospital.

PROVINCIAL MEDICAL SCHOOLS

In general it may be said that the provincial medical schools are acting entirely as evacuation areas. Newcastle-upon-Tyne, being a de-restricted area for air-raids, is not receiving evacuees. At Oxford it is probable that a complete clinical course for Oxford students will be organised at the Radcliffe. Teaching in most areas will probably begin earlier in the day and end earlier so that blackout difficulties may be avoided. At Newcastle work is to cease at 3.30. Many provincial schools have already been depleted as members of their staff have left for service appointments, but clinical teaching will not be seriously affected.

ORGANISATION OF A SECTOR

THE Government's scheme for the reorganisation of hospitals to be ready for civilian air-raid casualties has undergone modifications in detail since it was announced in March, but few changes have been needed in its framework. A year ago the Minister of Health divided England and Wales into twelve regions, each with a "hospital officer," usually a member of the Ministry's medical staff. This officer drew up a plan for placing the hospitals in his region on a war basis, and when war came he was responsible for putting it into effect. The general aim was to provide in the danger areas for the collection, first-aid attention and sorting of casualties, and for enough treatment at casualty-receiving hospitals to fit them for a journey by ambulance. Next, to provide advanced base hospitals in presumably safer areas, fully equipped in both apparatus and personnel to carry out all necessary operative or other treatment of the injured; base hospitals still further from danger to which patients could be moved for after-treatment; and, finally, a group of less well-equipped hospitals for convalescent and chronic cases. London formed one region, but on account of its dense population and liability to attack it required special consideration. The Metropolitan Police district and the area within about forty miles was therefore divided into ten sectors, radiating out from the twelve big London teaching hospitals, which were to be the main casualty-receiving hospitals for their sectors. Each of these teaching hospitals nominated one of its staff, often the dean of the medical school, as "group officer." His task was to allocate the work of the hospitals and personnel in coöperation with the hospital officers into whose regions his sector extended, and under the supervision of the Director-General of the Emergency Medical Service. He was not responsible, however, for the internal management of the hospitals, which remained in the hands of the governing boards or the local authority, as the case might be.

Sector V. makes a convenient example of the organisation, being one of the smallest. Its parent hospital and main casualty-receiving hospital is the Middlesex, and its group officer, Dr. H. E. A. Boldero, has his headquarters and secretarial staff in a private house at Rickmansworth. The number of available beds at the Middlesex has been reduced from the pre-war 614 to 320, and the medical staff now consists of 21 full-time men, mostly drawn from the junior members of the ordinary staff, and 40 students in their clinical years. In the first few days of the war the hospital was cleared of patients as far as possible by sending them home or to other hospitals, and for the first fortnight only urgent cases were admitted. At that time only 78 patients remained. Since Sept. 16, however, the Minister of Health has sanctioned the admission of semi-urgent cases from the waiting list. Windows, sky-lights and so on have been protected, but no great structural alterations have been needed to convert the buildings to their new purpose.

The sector contains seven other casualty-receiving hospitals "class 1A"—that is to say, hospitals of over 50 beds which were or have been made capable of giving the necessary immediate treatment to casualties—namely, the Central Middlesex, Harrow general, Wembley general, St. Andrew's Dollis Hill, Willesden general and Willesden infectious diseases hospitals. In most of these the number of beds remains about the same as before the war, though in some additions are projected. The buildings have

been given protection from air attack and additional equipment has been supplied by the Ministry of Health Their medical staff are not all full time, some being still in practice in the neighbourhood The Willesden general, for instance, has 6 full time and 4 part time men and 14 Middlesex students, the Harrow general 5 full time men living out, 2 resident house officers, 6 part time men and 12 students These hospitals have also been cleared of patients except for a nucleus of about a fifth of their complement In addition there are five casualty-clearing hospitals "class 1B"—Paddington Green, the Western Ophthalmic, the Samaritan Free, the Radium Institute, and Northwood and Pinner hospital—special or small hospitals that will only change over from their ordinary work to the reception of casualties when the organisation is hard pressed

Next come the two advanced base hospitals, the Mount Vernon and the Royal Bucks at Aylesbury The Mount Vernon has been greatly enlarged and is now equipped and staffed to deal with all kinds of injuries Before the war it contained 100 beds for cancer patients, now it has 520, 300 being in tents on the lawn, and when its hutted annexe is finished it will have 620 It has an entirely full-time staff of 29 as well as 24 students, mostly drawn from the Middlesex The Royal Bucks has had some 35 beds added to its pre-war 115, and also has some students attached The casualty receiving hospitals will send their patients when they are fit to move to one of these two, the intention being that the Mount Vernon will take patients from the Middlesex and its neighbourhood and the Royal Bucks from hospitals further out, though this must necessarily depend on where the main brunt of an air-raid falls

In most sectors the base is situated well away from London and arrangements have been made for the reception there of a large number of patients At Arlesley, for example, the base hospital for sector III, the Three Counties mental hospital has been extended to take 1200 casualties in addition to its 1100 mental patients Similarly, the base for sectors VIII and IX at Horton will have over 2500 beds In sector V, however, no comparable institution capable of rapid conversion was available, and the base is placed at Aylesbury close to the advanced base hospital For this purpose the Aylesbury public assistance institution is being enlarged and up graded by the erection of tents and huts and the addition of theatre and other equipment to hold some 700 patients The three remaining hospitals in sector V—Chesham cottage hospital, St Monica's children's hospital and the London lock hospital—may be needed later for the reception of chronic or convalescent cases Meanwhile, like the casualty receiving hospitals in class IB, they will go on with their ordinary work.

PANEL AND CONTRACT PRACTICE

Regulations Suspended

THE Ministry of Health have informed insurance committees that the regional medical service has been suspended and the regional medical officers assigned to other duties Insurance practitioners cannot, therefore, now refer cases to the R M O either to assess incapacity for work or for consultation Other activities under the medical benefit regulations which have been suspended until further notice are

(*a*) The routine testing of drugs and appliances supplied to insured persons Special tests may, however, be made where there are good grounds for thinking that tests are desirable, (*b*) Proceedings under regulation 43 for alleged excessive prescribing, (*c*) Proceedings under regulation 41 for the investigation of certification, (*d*) Proceedings under regulations 42 and 45 for failure to keep medical records The Ministry are not enforcing the obligation to keep records during the war, but are leaving practitioners to keep such records (especially clinical notes) as they can in the pressure under which they will be working It has been suggested that where the absentee practitioners' records are deposited with insurance committees they should be redistributed among the acting practitioners who have these patients on their temporary lists, for their information and completion This course also seems desirable from the point of view of the safe keeping of the records to avoid their concentration longer than is necessary in the offices of committees, (*e*) Proceedings under regulations 47 and 48 for substances alleged not to be drugs or prescribed appliances, (*f*) The routine checking of prescriptions against practitioners' lists The committee, however, is given discretion to deal with a particular case

More Cooperation and Larger Lists

The Ministry have suggested that for the period of the emergency insurance practitioners should agree to forgo payment from the local practitioners' fund for emergency treatment and anæsthetics It has long been the policy of some panel committees to discourage claims for emergency treatment on the ground that practitioners should act for one another in case of necessity on the principle of give and take

In view of the smaller numbers of practitioners available for civilian (including insurance) medical service some latitude will be found necessary in the maximum number of insured persons permissible on practitioners' lists General approval has been given in allocation schemes for an additional 500 to the maxima prescribed for practitioners with and without partners or assistants, and a similar increase in the average for a partnership This relaxation will be examined in the light of experience and the extension now allowed may even be increased

Prescriptions and Certificates

The Minister has been approached about insurance practitioners' surgery hours and insurance chemists' shops' hours of opening, in view of the blackout Though early closing would be convenient to doctors and chemists, and even many patients, it must be remembered that national needs will not permit all works and offices to close before nightfall The Minister has recommended insurance committees to review the position in consultation with the local panel and pharmaceutical committees and make suggestions The Minister has also said that it would help if practitioners always make a practice of issuing prescriptions and certificates to patients at the time of visiting them It is a little surprising to find that the Minister has found it necessary to make this suggestion

Absentee Practitioners

Large numbers of insurance practitioners have been called away Some have arranged for partners or deputies to carry on their practices on their behalf, but many have taken advantage of the B M A. scheme for the protection of practices So far as insurance practice is concerned, 50 per cent of the

remuneration of the absentee practitioner is credited to him and the other 50 per cent., less an amount to be determined in respect of the cost of administration, forms a pool from which acting practitioners are remunerated for their services. The bureaus to administer this arrangement are as a rule the local insurance committees During a practitioner's absence his list will be reduced in respect of deaths, cessations from insurance and removals outside the area of his practice; the ordinary end-of-quarter transfers will also operate, but he will continue to be remunerated in respect of those of his patients who have placed themselves provisionally under the care of acting practitioners.

So far as acting practitioners are concerned, acceptances during the war will be provisional and afterwards all patients will be given the option of exercising a fresh choice. Insured persons accepted for the first time, that is to say, new entrants and removals into the district, will carry 100 per cent. capitation value to the accepting practitioner, but provisional acceptances of the patients of absentee practitioners will of course rank only towards the distribution of the bureau pool. Acting practitioners would be well advised, when accepting patients of absentee practitioners, to take care that part "B" of the medical card is completed and that the word "provisional" is endorsed in that part of the medical card as well as their signature Insurance committees in their capacity as local bureaus will have to keep a separate record of this type of provisional acceptance, and practitioners will find that a little extra trouble in indicating the type of acceptance will be amply repaid in reducing misunderstandings.

As already indicated, the keeping of medical records will not be obligatory during the war, but some bureaus are arranging to supply specially marked continuation cards for provisional acceptances of patients of absentee practitioners, so that the acting practitioner may readily recognise the war-time patient and make any clinical note he may feel desirable. Practitioners who are leaving their civil practices to take up national service are reminded that they must communicate with the insurance committee and indicate the nature of the arrangements made for the conduct of their insurance practice It is difficult to believe, but we are told that some practitioners have gone on full-time national service without making any arrangements to secure the treatment of the patients for whom they are responsible and for whom they are being paid by the insurance committee.

GRAINS AND SCRUPLES

FROM D P.M.

V

Now that we have leisure to exchange views, I am finding out how different people prepared for war. One friend of mine bought herself a pair of ski-ing trousers and some sherry, and another laid in an eighty-pound cheese. Some have bought bicycles and some bedsocks, and one unearthed a piece of crochet she had begun in her first year as a medical student. When I reviewed my own preparations, I found I had chosen a pair of gum-boots and a Chippendale chair.

Amateur philosophers, luckily for everybody, are nearly as common as amateur generals in war-time. It is an old observation that an ordered routine makes people disgruntled whereas a crisis mellows them. You have only to compare the savage conduct of the average man and woman catching a bus in the rush hour with the coöperative, gay and unselfish behaviour of the same people during a transport strike; their humanity is delightfully stimulated by a little misfortune The same genial atmosphere prevails in any large railway station on the eve of a public holiday, when trains loiter off irresponsibly, hours behind their time, and good-humoured passengers sit round upon their luggage cracking jokes. I suppose the truth is most of us welcome a change and are prepared to believe that provided things are different they might be worse. Still even philosophy can be carried to extremes—or so I thought after hearing two of our more tranquil critics discussing the situation the other day. The conversation ran as follows:

"Terrible business, their sinking this warship"
"Yes—well—but it's war, I mean, isn't it?"
"Yes; I suppose we mustn't grumble."

* * *

The trouble about golf, an enthusiast tells me, is that the clubs face the wrong way. I cannot understand the finer points of his sorrow, but he seemed to be complaining that all the real work has to be done by the left hand—and backhanded at that. Anybody but a fool, he says, would use his right hand for such a ridiculous stroke; and, following the example of the Oldest Member, tells this illustrative story A parsimonious acquaintance of his who decided to take up golf went round the junk shops pricing secondhand clubs; finally he found a complete set going for a song and quickly bought them—only to find, of course, that they were left-handed. But the annoying fellow, anxious to get his money's worth, decided to play left-handed; and found his golf much easier in consequence.

The unjust moral makes one wonder whether we are all more ambidextrous than we think. Left-handed people, of course, are commonly ambidextrous, no doubt because the general right-handedness forces them to conform to many right-handed actions In digging most people seem to be almost ambidextrous. I call it right-handed to hold the handle of the spade with the right and the shaft with the left hand; this means that you stand with the left foot advanced and use a right-handed drive and a left-handed lift Most men claim to prefer this stance, but add that they can readily use either hand. Women seem to favour the left-hand stance, perhaps because lifting is accomplished more readily with the right hand; on the other hand, left-handed people also seem to prefer the left-hand stance It seems curious but not very interesting.

* * *

Psychologists have done us all a service by insisting that an adult state of mind is proper to adult people. That this notion was summed up long ago in the phrase "Ripeness is all" is no fault of theirs We know well enough by now that nothing new is to be found in the human mind, and they have done their part in bringing the idea once more to our notice Moreover, they have reminded us that the mature state is becoming to every grown person—to women as well as men.

Of course, one may argue, a mature state is not accessible to mankind. Human intelligence is strictly

limited, battering blindly against concepts which tower beyond its scope We shall never get the hang of the cosmos with the rudimentary brain at our disposal—a brain which cannot contemplate space or eternity with any sense of meaning Evolution will have to do better than this before some creature can lay claim to maturity in an absolute sense We can, however, become mature in a relative sense as mature as our natural equipment will suffer us to be, just like any other animal I have heard it suggested that this degree of maturity is insufficient for our needs, that we are not, for example, and never can be, mature enough to avoid war because our limited intelligence will never find another way out of a deadlock Without sharing this defeatist view entirely, I do believe that until we can think of a way to prevent wars we deserve them, stupidity is always punished by nature, and I can see no reason why we should be spared

If we are not mature enough intellectually to prevent war, we can at least try to be mature enough emotionally to put up with it, and, taken by and large, I think we are For this reason I am sickened by the phrase "Women and children first" Why women? Surely maturity implies the fortitude to bear one's lot, and the mature woman should be as capable of that as the mature man Let us, indeed, distinguish between grown people and children Children first, by all means, children are growing creatures and therefore vulnerable But let us finally get rid of this morbid notion that women should be classed with them as something incomplete, brittle, meet to be protected Women in England are fortunate in having emerged from the long exhausting battle for an equal share in responsibility with men, they are able to grow to their full mental stature in responsive surroundings When responsibility is increased by war they cannot be expected to regress to a state of semi dependence, or to accept a greater share of protection than others merely in virtue of their sex Posters showing a terrified woman clasping a child and cowering behind a square shouldered male are an insult to us all It seems to me far less justifiable to send youths of eighteen or twenty into active service than to kill grown women with bombs

* * *

Grain without Scruple "For every new public law they put upon me I propose to take off one private one"—Medical Officer, exasperated by the black out

LETTERS TO THE EDITOR

CONFLICTING EMOTIONS

SIR,—I have little doubt that many of my colleagues who are honorary members of hospital staffs in London read your leading article last week with the same conflicting emotions it produced in me You appear to share the easy optimism of the nameless correspondent you cite and ask us to accept with you as inevitable consequences of the present emergency a virtual paralysis of civilian hospital services, and a total inactivity and an early bankruptcy of the hospital staffs Offered to us as adequately offsetting this wreck of our work and our fortunes are the speculation that had massive air raid casualties ensued upon the outbreak of war we should now be hailing the emergency medical scheme as a triumph of organisation, and the consolation that our bankruptcy will not be discreditable

One would need to be of a more than German docility to accept these astonishing propositions If it be true that something more than bedsteads buildings, doctors and nurses are needed to provide an effective hospital service, we may be allowed to doubt whether, had heavy casualties occurred a fortnight ago, we should now be congratulating ourselves upon any triumph of organisation Robbing Peter to pay Paul can hardly be called organisation, and this is the essence of the scheme to which we are committed

Yet the method has it must in fairness be admitted, a good precedent Readers of Charles Lamb's "Dissertation upon Roast Pig" will recall how those eager organisers Bo he and Ho ti burned down their house to roast a pig, and it seems that the ordinary medical needs of the population have been quite effectively burned down to roast the emergency pig Nor does the parallel end here for as in that engaging fable the insurance companies were forced to "shut up shop" by this method of organisation, so now—as you so cheerily assure us—the hospital staffs must expect to follow their example in no long time

I cannot believe that some plan for meeting the special needs of the emergency and at the same time taking some account of the ordinary needs of the community is beyond human ingenuity if only it were attempted, and I reject your correspondent's easy acceptance of the present state of affairs as embodying "the long view" Indeed, there are grounds stated in the latter part of your article that justify profound dissatisfaction with the present chaotic position of medical affairs

I am, Sir, yours faithfully,

Sept. 25 ANOTHER CORRESPONDENT.

SIR,—I have read with appreciation the leading articles in your last issue, entitled The Hospital Services, Medical Libraries in War-time, and Safety First Although apparently dealing with different subjects, they all bear the same message—namely, that in spite of the disorganising effect of war, the civil life of the community, and incidentally of the medical profession, must still contrive to carry on

It is inevitable that in the hurry to meet the requirements of war the everyday needs of the population should have been neglected, but, you rightly point out, a breathing space has been provided during which we can look around and contrive how this neglect can best be rectified

The last few weeks have seen the consultants of the London area sitting idle in their lodgings, or, if fortunate enough to be still in London feeding the ducks in Regent's Park, while patients badly in need of attention were at their wits end to know where to turn for help Now, in the hope of avoiding this, the Ministry is about to substitute for whole-time service some form of half time service, and the consultants are at present wondering whether it is better to continue in the Park or their lodgings or else to accept a wage on which—considering their obligations—it is absolutely impossible to live, in the hope that eventually they will succeed in resurrecting some modicum of private practice

The answer whether it is better to be content with a certain half loaf or to accept an inadequate bite with the chance of earning a substantial piece of cake depends of course on the ability or inability of the civil population of London, including of course ourselves, to adjust to present conditions If nursing homes are to remain closed, libraries shut, radium buried, theatres locked up, business transferred to the country, and civil life generally at a standstill, it will

be better to continue reading our papers in our lodgings, or feeding the ducks in Regent's Park. If, however, civil life is revived, and if consultants display a readiness to adjust to new conditions, to make long journeys at reduced fees, to operate in country nursing-homes without charging mileage, and to coöperate in every way possible with those to whom is now chiefly entrusted the medical care of the civil community, then the wastage of public money and of private time that the last two weeks have witnessed can be avoided

"We've *got to be prepared*" it is true, but prepared not only for war but also for the ordinary business of living For two years during the last war I lived an exceedingly happy life in the pleasant city of Arras. Although the line was less than a mile away, and although at night machine-gun bullets could be heard spattering on the houses, civil life still continued, so that calling in at the chemist's shop in the main street I was able to purchase a tube of chinese-white paint of which, as an amateur artist, I had happened to run short Surely the spirit of the civilian population of Arras is the spirit that is required in order to win a long war

I am, Sir, yours faithfully,

Harley Street, W., Sept. 25. KENNETH WALKER.

AIR-RAID PRECAUTIONS

SIR,—With reference to D P M 's article in THE LANCET of Sept. 23, he seems to have forgotten that shells and bombs *can* produce wounds as bad as any of those he humorously refers to The Poles are not finding the lack of precautions against air-raids even in outlying districts particularly funny just now; what is there to justify the sneers of D. P. M and his Spanish girl friend? Did Guernica enjoy the bombs? Was the Spanish civil war such a picnic? Are the 200,000 beds awaiting air-raid casualties just another sign of our fussiness?

I am, Sir, yours faithfully,

Folkestone, Sept. 24. G. F. JONES.

FATAL AGRANULOCYTOSIS

SIR,—The admirable account by Mr. Nicol and Dr. Freedman in your issue of Sept 16, of a fatality following administration of M. & B. 693, is a valuable addition to the medical literature on agranulocytosis It is of particular interest in being the first recorded case of death from agranulocytosis in a patient receiving the drug for the treatment of gonorrhœa. The patient was elderly (60) and well above the average age of cases of gonorrhœa, but in the absence of liver and kidney dysfunction advanced age has not hitherto been regarded as an indication for reduced dosage. In this case, the dosage used was high and prolonged, but no more than has been used for many cases that showed no serious signs of intolerance

The manufacturers of M. & B. 693, in a brochure on its use in genito-urinary infections, state:

"Transient reduction in granulocytes is a not infrequent phenomenon in patients undergoing treatment by drugs of this group; but with the amounts of the drug used in the treatment of gonorrhœa damage to the hæmopoietic system is unlikely. It has, however, been reported in a few cases treated with M. & B 693 for gonorrhœa, but in each case the dosage has been in excess of 30 grammes, a total considered more than sufficient by many observers.

"It is probably a counsel of perfection to suggest that repeated differential white cell counts should be a matter of routine in all cases receiving sulphonamide drugs, and even with frequent blood counts it has not been proved that this will prevent deaths from agranulocytosis. Possibly the surest method of reducing the risk of such a rare but dangerous form of intolerance will be to limit the length of time over which the drug is given to an optimal minimum not yet determined. . . ."

It would be of value if venereologists could pool their experience and arrive at an agreement as to what constitutes the most effective daily dosage and optimal minimum period of treatment

I am, Sir, yours faithfully,

ROBERT FORGAN.

Pharmaceutical Specialties (May & Baker) Ltd, Dagenham, Sept 22nd.

PREVENTING VACCINATION SEQUELÆ

SIR,—Dr. Jameson may be right in advising the application of potassium-permanganate compresses to vaccinal lesions on the sixth day. But one may question the statement that "by experiment it has been shown that if a subject be vaccinated daily, on the fourth or fifth day the vaccination ceases to take; also if the vaccination area be excised on the fifth day, subsequent vaccination does not take." Cory[1] found daily vaccination successful up to the ninth day. He vaccinated a supernumerary digit, amputated it on the fifth day, and successfully revaccinated the child a month later. He pointed out the precocity and acceleration of revaccinations; his observations were confirmed by Pirquet's investigations of allergy.

It would seem to be misleading to say that "vaccinal immunity is therefore established on the fourth or fifth day," unless experiments with modern lymph have invalidated the older work. Dr. Jameson may nevertheless be right in his opinion that "nothing is lost by disinfection of the vaccinal area on the sixth day," as clinical and experimental evidence suggests that the virus is frequently generalised throughout the body at that time.

I am, Sir, yours faithfully,

PHILIP EVANS.

King's College Hospital, S E 5, Sept 23.

TOWN AND COUNTRY NITS

SIR,—Your issue of Sept. 16 gives (p. 674) the percentage of verminous children in some South Country schools. A month ago the rural schools in the North Riding of Yorkshire were nearly 100 per cent. clean Whatever the percentage may have been at Gateshead and Leeds, they must have inadvertently selected that percentage to send as evacuees into our district The children were nearly *all* verminous. The horror of the hostesses of these children, whether in cottage, vicarage or big house, was indescribable. Tooth combs and Derbac soap were sold out in Northallerton before the end of the week; the only subject of conversation on market-day was the best methods of delousing. The babies and toddlers were in the same state, and what shocked the country folk more than all was the supine attitude of the evacuated mothers towards the pest. Doubtless they were in the same state themselves. We shall send the school-children back to their parents clean (and with, I hope, improved health and table manners), and when the war is over and we can turn our attention to setting our own house in order, cannot a campaign be set in motion to civilise our own towns A terrible state of affairs has been revealed by the manners and customs as well as the dirty condition and habits of many of our evacuees

I am, Sir, yours faithfully,

PHYLLIS M. JOHNSON.

Mount Grace Priory, Northallerton, Sept 24.

THE BURDEN NEUROLOGICAL INSTITUTE

SIR,—In view of the difficulty that must be experienced in obtaining inpatient treatment for cases of nervous and early mental disease occurring in evacuation areas I should be glad if you could bring the services offered by the Burden Neurological Institute to the notice of your readers The institute would be prepared to receive a number of cases of early mental disease for a course of shock therapy, and cases of organic nervous disease including cerebral tumours for investigation and if necessary operation The institute which was endowed by the late Mrs Burden is fully equipped both for neurosurgery, shock treatment and endocrinological investigation

I am, Sir, yours faithfully,

F GOLLA

Stoke Lane, Stapleton, Bristol, Sept 23

LONDON VOLUNTARY HOSPITALS EMERGENCY BED SERVICE

SIR,—On the outbreak of war, by a prearranged plan the whole staff of this service was taken over by the Ministry of Health as part of the Ministry's emergency medical service to assist in running the sector casualty bureaus In consequence, the emergency bed service was closed down A new staff has now been recruited and the service will reopen forthwith and will endeavour to assist doctors to obtain admission for their acute or emergency patients In the first instance it will only be possible to run a daytime service (9 A.M. to 10 P.M.), but it is hoped to restart the full 24 hour service *as soon as* the staff are sufficiently trained

I am, Sir, *yours faithfully*,

R E PEERS,

Secretary, Joint Committee of the King's Fund and the Voluntary Hospitals Committee

10, Old Jewry, E.C.2
Sept 25

PUBLIC HEALTH

Obstetric Appointments in Receiving Areas

In a letter addressed to medical officers of health in the receiving areas on Aug 25, Sir Arthur MacNalty made it clear that the arrangements for the care of expectant mothers evacuated to their areas were the responsibility of the local supervising authorities The maternity work involved, he said, should be under the clinical supervision of an obstetric specialist or specialists, who should be in charge of the maternity unit for complicated cases These specialists should also act as consultants for antenatal cases of doubt or difficulty, in the treatment of women suffering from serious illnesses of pregnancy, in complicated confinements and in the treatment of *puerperal sepsis* He suggested too that one or more medical officers with sound obstetric experience might be needed to act as residents in the larger improvised maternity homes and to assist the specialist in other directions The local emergency committees of the British Medical Association were to be consulted on the matter of personnel and if obstetric consultants of suitable standing were already employed by the authority, their services should be utilised for this work Local authorities have had time to consider their needs, and the Minister has now asked for their proposals

The officers will be appointed and paid by the local authority, the salary scales being based on those of the Emergency Hospital Medical Service Whole-time obstetric specialists (non resident) will be paid £1300 a year, the salary of a group officer Part-time specialists will be paid a proportion of that salary Obstetric officers who act as residents either at the hospital unit for complicated maternity cases or at an improvised maternity home will be paid £550 a year, the salary of a medical officer under the emergency hospital scheme In some cases two or more authorities may combine and make a joint appointment, or the officer's time may be divided between surgical and obstetrical work The appointments will be for six months in the first instance A number of them have already been made

Hospital Treatment for Non-Casualties

The Minister of Health has taken further steps to make it generally known amongst the hospitals that patients whose medical condition necessitates inpatient treatment should be immediately admitted. This "reflux" into the normal hospital accommodation was always provided for in the Ministry's scheme. To meet it, new beds are continually being added, so that on balance the number held in reserve for casualties will not be seriously diminished The figures received by the Ministry each day from the regional hospital officers show that this is in fact taking place Outpatient departments are continuing to function and are being reopened at a number of hospitals where they had been temporarily closed

EPSOM SALTS

MANY observers have studied the cathartic action of $MgSO_4$ on the bowel, but several of its features have remained obscure Clearly the salt, whether in dilute or concentrated solution, induces hypermotility of the gastro-intestinal tract, and it is also known that it causes secretion, but it is not certain whether secretion alone is responsible for the increased bulk or whether transudation also plays a part In experiments on cats, Lium and Florey noted[1] that a single dose of magnesium sulphate even in isotonic solution, might cause not only one watery motion but a continuance of such motions for some days and after the magnesium has been excreted A similar effect in man has also been noticed, and is attributed to a slowing of the absorptive capacity of the bowel Another possibility, that the prolonged action is due to irritation of the intestinal mucosa, was explored histologically by Lium and Florey, but they found no more evidence of irritation with magnesium sulphate than with sodium chloride, although the appearances were consistent with secretory activity They also tried to determine the action of the magnesium and ordinary salts on defæcation in cats Magnesium-sulphate solution, in quantity comparable to that which causes purgation when given orally, was injected into the colon through an appendicostomy opening and the result was a defæcation attributed to the mechanical action of the increased bulk of the intestinal contents Sodium chloride had no such effect It was observed also that isotonic magnesium sulphate slowed the absorption of isotonic sodium chloride from the intestine, but did not influence the absorption of glucose solution

The poisonous effect of magnesium sulphate is described by F. E. Byron, who reports[2] five cases in which Tamil children, aged 2½ to 5 years, died within two hours of single doses of this drug

OBITUARY

SIGMUND FREUD

M.D., LL.D., F.R.S.

Professor FREUD died on Sept. 23 at his son's home in Hampstead at the age of 83. He had been living in England for the last year since leaving Vienna after the Nazi coup d'état. Though psychoanalysis had been banned by National Socialism, Freud was kindly treated and allowed to bring with him his books and papers. A doctor by profession and a psychotherapist by occupation, he was essentially a scientist, with all the scientist's constant preoccupation with truth. To describe him as a philosopher is wrong; he was an observer of the mind, piecing together his findings with infinite patience, always prepared to admit himself wrong and indeed frequently doing so, rather than an abstract seeker after the nature of good and evil trying to square himself with his environment. When National Socialism and Fascism are merely turgid pages in the world's history, Freud will still be honoured. He founded the science of psychopathology. He developed the technique of psycho-analysis for its investigation. If he became the centre of a controversy as violent as that surrounding Darwin and Huxley, he had one advantage which was denied to them. He knew the reason for his opponents' opposition and in it he found fresh confirmation for his own case. It has been wittily remarked that man's self-esteem has suffered three great blows. The first was when Galileo demonstrated that the earth was not the centre of the universe but merely a small planet revolving round the sun. The second was when Darwin announced that man, traditionally made in the image of his Creator, was a product of evolution from the supposedly lower beasts. And the third was when Freud showed that the final crowning of man's achievement, his infinitely adaptable and creative mind, was nothing more than a sublimation of the baser instincts.

Sigmund Freud was born at Freiburg in Moravia on May 6, 1856. He was a brilliant youth, at the top of his class at the Vienna Gymnasium for seven years, enjoying special privileges. But both here and later at the university, no matter what his attainments, he found that as a Jew he was expected to regard himself as inferior. This he resolutely refused to do. His interest was a diffuse curiosity towards human concerns rather than a specific love of medicine, and it was the influence of Darwin's work and Goethe's nature studies which in the end determined his choice. Apart from psychiatry and neurology, medicine proper had no particular attraction for him and he was negligent in his studies. But he soon began to show an outstanding ability at research, first in the physiological laboratory and then the institute of cerebral anatomy. His first publications were monographs on aphasia and cerebral diplegia in childhood. But there was little scope for private practice in neuropathology and Freud quickly perceived that certain other aspects of nervous disease were entirely ignored in Vienna at that time, so he resolved to turn his attention to the neuroses. The treatment of these conditions was still a matter of crude empiricism. They were inaccessible to the physical methods of investigation by microscope and test-tube which were then yielding a rich harvest in the study of more obvious physical disease. To this attitude there was one important exception. Charcot at the Salpêtrière was studying the neuroses as a scientist. So in 1885 at the age of 29 Freud went to Paris. What he saw convinced him that hypnosis was something more than a smart trick or a fraudulent publicity stunt. In Charcot's hands hypnosis could induce artificial diseases which conformed exactly to conditions familiar in the hysteric. *Hysteria was no longer something* beyond the pale of scientific investigation; it conformed to laws, though these laws were not in a province familiar to doctors of the day.

On his return from Paris Freud married and settled down as a specialist in nervous diseases. But his new points of view and original methods of approach brought him immediately into difficulties with his colleagues. Opposition and ridicule greeted his *reports. The laboratory of cerebral anatomy* was closed to him; and finally he withdrew entirely from academic life. Left alone at the age of 30 with his private practice in nervous diseases, he soon discovered the uselessness of such fashionable remedies as electrotherapy and so set out in search of some method based upon scientific findings. At first he used hypnosis only as a positive instrument to give commands. In a joint investigation with a senior friend, Josef Breuer, *they made the remarkable discovery that a* hysterical patient under hypnosis was able to reveal the meaning of certain of her symptoms in terms of her past life. They found to their surprise that as these secrets were revealed so her condition improved. On the basis of this and some similar experiences a "cathartic" method was evolved, and in 1893 their book "Studien über Hysterie" was published. Four years previously Freud had attended Liebault's and Bernheim's *astonishing demonstrations in hypnotism* at Nancy and had there become convinced that powerful mental processes could exist which nevertheless remained hidden from the consciousness of man. In "Studien über Hysterie" the distinction between the conscious and the unconscious was stressed and the importance of the emotions in mental symptoms began to come to light. But differences between Freud's view and Breuer's were even then obvious. Freud *suspected an interplay of opposing forces in the mind,* while Breuer inclined to a more physiological conception.

In the next fifteen years, as a result of concentrated and almost completely isolated clinical work, Freud built up his system of psychopathology and psychoanalysis. Each step followed logically though at times setbacks occurred. He soon discovered that the suppressed emotions and memories which were unearthed by hypnosis were of an erotic or sexual nature. He found that in investigation of the neurotic patient, transference-love invariably developed between the patient and physician. He did not attribute this to his own attractions, nor like Breuer fly from it as a danger. He came to realise that transference represented a displacement of affect, that in these patients there was, as it were, a quantum

of labile emotion ready to attach itself to any convenient object

As his experience increased he found certain disadvantages in hypnosis as a technique Some patients refused to be hypnotised, while in others an unconscious resistance to recall was encountered Two steps followed The first was the recognition that forgetting and not knowing about past emotional experiences was a positive rather than a negative phenomenon Powerful forces were at work to exclude unpleasant realities from consciousness, so the theory of repression was born A neurosis was seen as an outlet for this suppressed emotional energy, an unsatisfactory and antisocial mental satisfaction The second step was the development of a technique which obviated the necessity for hypnosis This was called free association If a person speaks at random the first things which come into his mind, the choice is found not to be the random one, as one might expect, but rather to be determined by dynamic mental processes in the unconscious A prolonged series of interviews at which the patient speaks in this manner reveal to an astounding extent the mental processes and events which were emotionally significant in his past life The unearthing of these hidden traumata is the essential part of the technique of psycho analysis Although developed as a therapeutic method it is by no means always a practical procedure It requires a considerable amount of intelligence in the patient, not to mention an infinity of patience in both patient and doctor Further, therapeutic results are not invariably satisfactory For these reasons, apart altogether from the surprising and to many people unpleasant content of the unconscious, psycho analysis has met with much opposition Yet looked upon as a method of investigation of the unconscious mind all unbiased psychopathologists must admit its value

The work of searching for forgotten memories led over further back and slowly revealed the importance of children's sexual practices and their wishes and fantasies relating to sexual things At this point a dramatic crisis arose which threatened to overwhelm both the research and its author He constantly unearthed experiences of sexual seduction by adults in the childhood of his patients and to these he attributed a traumatic action in the cause of their neuroses But he was at last obliged to recognise that many of these were actually untrue in fact and figments of the imaginations of his patients This realisation seemed to undermine the whole of his work But he kept on He found that symptoms were undoubtedly associated with these episodes, though the episodes themselves were imaginary They were fantasies and wishes often interwoven with memories of real sexual acts and forgotten practices with other children Without knowing it Freud had stumbled here upon the Œdipus complex That the love of a child for a parent could be sexual was an epoch making discovery which perhaps more than any of his other findings aroused resistance among those who did not wish to see themselves as they really were

If the neuroses furnished the first clue to the existence of the unconscious mind three other lines of investigation provided ample confirmatory evidence In 1900 he issued his "Interpretation of Dreams" In it he showed that the apparently nonsensical nature of the average dream became a matter of commonsense simplicity if it was realised that the dream represented in symbols compatible with consciousness the sexual desires of the unconscious mind The work was met with indifference or laughter. He was not dismayed but asked himself why his readers laughed This led on to his studies of humour and wit Here again he found that the conscious defended itself from the unpleasant in the unconscious by treating it as a joke His conclusions were recorded in his book, entitled "Wit and its Relation to the Unconscious" The third investigation which helped to clarify the situation was that on the Psychopathology of Everyday Life, published in 1904 He observed that trivial events such as forgotten appointments, requests neglected, and even the random choice of figures, were actually determined by unconscious wishes or fears

From this time on his isolation came to an end A circle of pupils gathered round him in Vienna and he was encouraged by the interest of Bleuler and Jung at Zurich In 1908 the first informal congress meeting was held at Salzburg, but as psycho analysis became more widely known so opposition to it extended Then in 1909 he was invited to the United States to lecture at Clark University The event seemed to him like a day-dream In Europe he was despised, but "here psycho analysis was no product of delusion, but a valuable part of reality" Three years later Adler and Jung parted company from him Each singled out one feature of mental life and stressed it above all the rest Freud only insisted that they should both cease to describe their views as psychoanalysis During and after the war psycho analysis steadily gained ground If it attracted to its ranks some who by their mental instability were fit rather to be patients than prophets, it safeguarded itself by insisting that none should practise true Freudian analysis who had not themselves been fully analysed The vast body of knowledge of the unconscious mind which the host of workers in Europe and America have now built up is unfortunately all too often incomprehensible to any but the elect Psycho analysts have seldom followed their master in the expression of their views in simple everyday language The mysteries of the craft are hidden in polysyllabic jargon and the output of literature is more impressive quantitatively than qualitatively

But Freud's work still stands four-square The existence of the unconscious mind has been established beyond cavil The mental processes of repression, sublimation, transference, and symbolism are now commonplaces Whatever the ultimate judgment of psychiatrists on psycho analysis as a therapeutic technique, there can be no doubt that as an explanation of the symptomatology not only of hysteria and the anxiety and obsessional states, but also of schizophrenia, paranoia and depression, Freudian psychopathology is of fundamental importance What Virchow was to the body, so Freud has been to the mind The microscopist and the analyst fill in the gaps The structure itself is sound

AN INTIMATE IMPRESSION

A colleague writes. "When I knew Professor Freud in Vienna in 1922, he was aged 65 and more or less at the height of his career Soon after 1910 the solitary obscurity which had surrounded him and his work for something like 20 years had begun to lessen, while the war neuroses in Europe had generated, both in the medical profession and in the general public, an interest in the psychological approach to such disorders This had brought his work into the foreground and made his name known In 1922 he and his followers in Vienna Berlin and Budapest were fully occupied with teaching and training (first and foremost by analysing them personally) the group of English, American and Swiss physicians and others,

who were taking up the new study of psycho-analysis. A few years later, in 1924, the serious but successful operation on his jaw caused him ill health at times, though it affected only slightly his capacity for work and his speech. He afterwards went about even less than formerly, and the future will probably judge his later work as falling short in various ways of his earlier achievement.

"I had met Professor Freud at The Hague in 1920, at the first International Congress of Psycho-Analysis held after the war. He impressed one as an exceptional personality. His appearance was not typically that of a medical man, nor was it particularly Jewish. The long pale face with grey beard and stooping shoulders were those of an intellectual and might have suggested a learned professor, but for two other essential characteristics. There was his lean but broad and sturdy figure, the rather stern expression and firm jaw, which bespoke a great reserve of dignity and hidden strength—an indomitable tenacity. He appeared somewhat aloof, in fact he could easily be bored by crowds and gatherings. His most striking feature, however, was the forward thrust of his head and critical exploring gaze of his keenly piercing eyes. Finally, this rather awe-inspiring appearance was lightened by the glow of an enchanting humour, always latent and constantly irradiating his whole person as he spoke, which reassured one that the Olympian was indeed a mortal too. I knew already from his writings of his astonishing knowledge of literature, of his memory, especially for Shakespeare; and of his other tastes, his love of all antiquities, of Greece and Rome and the art of earlier cultures. But on this occasion I first realised his amazing command of the English language. Although he had not been in England for over 40 years, his contribution to the scientific work of the small Congress was an extempore lecture given with absolute mastery in the simplest and most perfect English without any notes.

"These impressions were confirmed during 1922 when I studied with him and got to know him. Like his psychology, his personality was really one to concern itself with individuals. The aloofness, which was never indeed coldness or hauteur, but rather indifference to superficialities, vanished and one met a vivid, eager mind seizing on every detail with astonishing interest and attention. The vitality, the current of his great energy was felt. How he disliked preambles and polite nothings! My first analytic hour with him he opened—contrary to rule and inadvisably—saying, 'Well, I know something about you already; you had a father and a mother!' meaning of course, 'Quick, I can't wait for you and your inhibitions, I want something to start with; give me an outline to get hold of!' He would allow himself liberties with his medium, like any master, until he recognised a new problem and bent himself as a student to that.

"But whether in analysis or not, his interest, with all its intolerance of preliminaries and imperativeness, was curiously impersonal. One had always the impression of a certain reserve behind the eagerness, as though it were not for himself that he so peremptorily demanded to understand things, but for some purpose outside himself. There was a simplicity in this impersonal eagerness that was perhaps the most significant thing about him. He was so concentrated on the inquiry he was pursuing that his self functioned only as an instrument. His penetrating attentive eyes had not only the simplicity and innocent clearsightedness of a child—one for whom nothing is too small, and nothing either common or unclean—there was also in them a mature patience and caution, and detached inquiry. The half-peering and half-piercing gaze beneath the heavy brows showed a power to see beneath the surface and beyond the boundaries of ordinary perceptions. But it also expressed a capacity for patient, careful scrutiny and for suspended judgment so rare as to be unrecognisable by many; his cool scepticism has even been misread as cynicism or pessimism. There was in him a conjunction of the hunter on an endless trail and the persistent, immovable watcher who checks and revises, it was from this conjunction that his power of discovering and understanding the sources of the feelings and behaviour of men and women sprang. Indomitable courage and tenacity, coupled with an unswerving honesty, were the characteristics supporting his gifts of observation, his 'intrepid imagination' and insight, which led to his great achievements. Both these capacities, the power to see new facts and to check his observations, diminished considerably in him after his operation in 1924.

"Along with these qualities, to which essentially we owe his great work, his personality had many very human features which endeared him to his friends. The inimitable dry humour of his writings became in ordinary intercourse a charming gaiety and capacity for finding amusement in most situations; and though he could be tolerant and philosophical, he was apt to be both impatient and intolerant. His humour was often witty and barbed, and he could be choleric, resentful and unforgiving. Nor would I claim that he suffered fools gladly. He was compelled by destiny to be a great man in his work, but he lived his private life as an ordinary man, and he believed in that kind of life. He disliked pathological types and extremes of any kind. From this attitude of mind his intolerance of religion in my view largely derived, for religion tends to see life in black or white and cannot accept the compromises and complexities in it which are the subject matter of scientific psychology. Once when a heated discussion on political topics arose, he was accused of being neither black nor red, Fascist nor Socialist, his amused reply was, 'No, one should be flesh colour'—the colour of ordinary men. And again, apropos of a young scientist interested in psycho-analysis who might have proved of service to the new science, Freud said to me mournfully, 'But I can't regard it as normal, you know, that he has married a woman old enough to be his mother.' I could but laugh at the discoverer of the Œdipus complex, and he met the laugh with a twinkle, but he was seriously disappointed.

"In later life a certain reserve, dislike of publicity, and a concentration of interest on his work was characteristic of him; one surmises that this trait had developed as a result of the hostile reception for so long accorded to his discoveries. But he was no capricious hermit; numerous eminent contemporaries, especially in the literary world, sought his acquaintance and met or corresponded with him; among these were notably Romain Rolland, Thomas Mann, Arnold and Stefan Zweig. But any genuinely inquiring visitor, too, could always see him, and met with a frank and friendly reception. Whatever the outcome of the interview, those who preferred fair dealing to favours found nothing in him to alienate them. Above all, Freud was entirely without pose. He could be mistaken, but deception or disingenuousness were not to be found in his nature, and this essential honesty was the hall-mark of his mind. He wrote: 'I can say I have made many beginnings and thrown out many suggestions. Something will come of them in the future though I myself cannot tell whether it will be much or

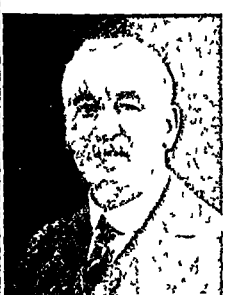
little' These words sum up and express the fearlessness, the acceptance of truth and love of it which characterised him and inspired his work"

GEORGE REDMAYNE MURRAY

M D CAMB, F R C P

FEW medical men have been so friendly to their colleagues and so beloved by them as George Murray, who died at his home, the Manor House, Mobberley, Cheshire, on Sept 21 For many years he had been ailing with cardiac pain on exertion Lately when prevented from taking active exercise he retired from practice as a physician

Born at Newcastle on Tyne on June 20, 1865, the son of a famed physician Dr William Murray, he was educated at Eton, of which he was always an attached alumnus, and at Trinity College, Cambridge From Cambridge he passed on to University College, London, where he took the Fellowes gold medal and qualified in 1888 Then came a year or two of study in Berlin and Paris and after this he commenced practice in Newcastle It was when he was lecturer at Durham University in bacteriology and comparative anatomy that he did the piece of work which has made him world-renowned In July, 1891, at the Bournemouth B M A meeting he read a Note on the Treatment of Myxœdema by Hypodermic Injection of an Extract of the Thyroid Gland of a Sheep It was soon discovered that given by mouth the remedy was equally potent in dispelling the symptoms of myxœdema, and the use of the remedy in cretinism quickly followed



J Ingham and Sons

In 1893 Murray was appointed Heath professor of comparative pathology and from 1898 to 1908 he was physician to the Royal Victoria Hospital, Newcastle In the latter year the chair of medicine at Manchester became vacant by the death of Julius Dreschfeld One of the terms on which the university had then recently given the site of Manchester Royal Infirmary to the trustees was that if the university appointed as professor of medicine a man not already on the infirmary staff he should become an honorary physician and have the care of a fifth of the medical beds The choice of Murray for the vacant post raised a storm of local opposition Murray, having accepted it, avoided controversy and by his friendly attitude to all around him and by his worth as a physician, soon made things work smoothly so that in 1925, when he retired from the active staff, the medical school *Gazette* wrote "With his curious lack of self consciousness and a personal charm which in itself amounts to genius, he has made an ideal representative of a great university I do not think I have ever had a conversation with him however brief from which I have not learnt something of interest expressed or implied I have never seen him angry I have never known him bad tempered Always he has proved himself a friendly and kindly adviser"

During the war Murray served in the R A M C with the 2nd Western General and the 57th General hospitals, later, as temporary colonel in the A.M.S he was consulting physician to the British Forces in Italy (1918–19) Many honours came to him He was a deputy lieutenant for the county palatine of Lancaster, president of many medical societies, including the Association of Physicians, and Goulstonian and Bradshaw lecturer Honorary degrees of M D were conferred on him by Durham and Dublin and the former gave him the D C L As a statutory commissioner for Durham University he took an active part in the rearrangements there

He was a man with many friends, we need only mention Victor Horsley, Michael Foster, Humphry Rolleston and John Cowan At Eton and Cambridge he was a keen oarsman, rowing in the Eton boat at Henley in 1883 Later, fishing was his chief hobby, and this with shooting and gardening filled in his spare time His widow was the daughter of E R Bickersteth, F R C S, of Liverpool They had one daughter and three sons, of whom two lost their lives in war service To Mrs Murray the Medical Benevolent Fund in the district owes a deep debt of gratitude

WILLIAM CALDWELL

M D, S C D DUBL

THE sudden death of Dr Caldwell at his home in Harcourt Street, Dublin, on Sept 1, has caused widespread regret In normal health, as far as he knew, until a few days before, he was seized by an anginal attack, from which he rallied, but which recurred and proved rapidly fatal Caldwell, who was born in co Antrim, was educated at Queen's College, Belfast, where he took a degree in science He was then appointed assistant to the late C H Thompson in the school of physiology at Trinity College, Dublin After Thompson's death in 1918, having in the meantime taken the degree of Sc D Dubl, Caldwell accepted the chair of physics and chemistry in the school of the Royal College of Surgeons While performing the duties of this post he found time to take his medical course in Trinity College, qualifying in 1930 Having resigned his chair he built up a considerable general practice As a teacher Caldwell was clear, painstaking and much interested in his pupils, as a practitioner he was popular with his patients and colleagues He leaves a widow and three sons, one of whom is in practice and another nearly completing his medical course

---

SIR JOHN LYNN THOMAS who died at his home in Cardiganshire on Sept 21 at the age of 78, was one of the great figures in Welsh surgery He was a student at the London Hospital, where he qualified in 1886, and after doing house appointments there he returned to his native Wales to become first a resident and then a surgeon at the Cardiff Royal Infirmary He was in charge of the Welsh Hospital in South Africa in 1900 and, as deputy inspector of military orthopædics, helped Robert James to organise that side of the army medical services in 1914–18 Since then he and his colleagues have made the Prince of Wales Hospital at Cardiff an orthopædic centre for Wales and he has played a big part in establishing the Welsh National School of Medicine Lynn Thomas was made C B for his work in South Africa and became C M G in 1917 and K B E in 1919 He retired from practice eighteen years ago He leaves two daughters

PARLIAMENTARY INTELLIGENCE

ON THE FLOOR OF THE HOUSE

By MEDICUS, M.P.

PARLIAMENT was grappling last week with some of our new problems on the Home Front There is the problem of organisation of supplies and the problem of profiteering, about which many complaints were made. But the very great change in our lives, that of the redistribution of population brought about by the evacuation of school-children from the cities, preoccupied the minds of most members. This evacuation problem and the allied one of civil defence of the cities and vulnerable areas have to be settled in the House of Commons. On military questions the House must and does act according to the advice of the military advisers; on the home front it is the M P s, the local government representatives and the national and municipal civil services who are the advisers.

It is already clear that the new rural population of children and women will need new medical and social services. The food service, speaking generally, is going well and the provision of a communal meal for all school-children in rural areas will help with and facilitate distribution. More attention is being paid to the conservation of human resources in this war than ever before, and one questioner elicited the reply that medical, dental, metallurgical and biological students will not be used for what was described as "normal combatant duties." The questioner stated that this would produce "a population of twittering scientists." But this somewhat Blimpish point of view got little sympathy. To waste medically and dentally trained personnel on ordinary combatant duties is clearly bad military organisation, although the difficulty will be to prevent such students getting away from their studies in order to do combatant work Most young men want to do it It is particularly necessary to conserve the members of medical services because the training is necessarily long and the supply of personnel only just enough. It is to be hoped that no romantic militarists will be let loose in this field or they may seriously damage our military efficiency.

* * *

A point of some importance which came up at question time was that of the pay of trained nurses According to an answer given by the Minister of Health to Captain Elliston, this pay is to be £90 a year plus board, lodging and laundry. But in a number of cases nurses have been enlisted by local authorities for mobile first-aid posts and other A R.P. duties and put on the scale of £2 a week, all inclusive, which is applicable to trained first-aid workers without nursing training in the ordinary sense. The matter appears to be due to one of the temporary dislocations fostered by the war, but it should be remedied at once as it is causing grave hardship in many cases On this point too, why the difference in pay between men and women A.R.P. workers? The flat-rate for men is £3 a week but for women only £2 There is no doubt a case for differential rates of pay because of different duties performed. But if the duties are the same? And if the women members of the services have responsibilities for ailing relatives and children, as many have, should they not get the same rates as men with similar responsibilities?

The new time scale of parliamentary proceedings came out very clearly on Wednesday, Sept. 20 Questions and the Prime Minister's statement on the war situation—the weekly statement—occupied from 2 45 until 6 45 P.M. After this the second reading of a bill was taken which deals with possession of mortgaged land under the emergency provisions arrangements. This is the type of bill which in ordinary times would have occupied a whole session of debate from 4 P.M. till 11 or even later. Last week it occupied 26 minutes, and the House adjourned at "thirteen minutes after seven o'clock." It is not only that members, like other people, want to get home in daylight, for some debates have recently lasted till nearly 11 P M. But all discussions now have a different perspective of importance. The other major debate of last week was on the Ministry of Supply and ... on until after 9.30 P.M. and the Government did not have too easy a time Mr. Greenwood for the Opposition expressed a very clear disagreement with the "non-possumus" attitude of some senior civil servants It was Pitt, I believe, who, on someone speaking of "impossibilities," got up on his gouty feet and said he was standing on impossibilities. The Labour movement, and particularly the T.U.C. and the skilled trade unionists, mean to pull their weight and insist that in this business they must be "in on the ground floor."

* * *

And so we turn to the War Budget The last Budget introduced by Sir John Simon attracted very much less parliamentary attention than usual because of the international situation. But the War Budget will certainly attract a great deal and Parliament will discuss it on Wednesday, Thursday and Friday By the time these words are in print we shall all know where we stand. Speculation on details is in vain But the general hope is expressed that we do not try and finance the war by borrowing on too great a scale

QUESTION TIME

SEPT. 21–22

Medical and Dental Students and Combatant Service

Rear-Admiral BEAMISH asked the Secretary of State for War whether his attention had been drawn to a letter issued to Cambridge undergraduates in which it was stated that medical students, research or post-graduate students in engineering, metallurgy, chemistry, physics, mathematics and biology would not be used for normal combatant service, and whether this was issued with the approval of his department—Sir V. WARRENDER (Financial Secretary to the War Office) replied: I have not seen the letter referred to, but it has been agreed that medical and dental students who have attained a certain stage in their medical and dental studies should complete those studies with a view to medical or dental employment with the forces or as civilians. Arrangements have also been made to secure that the services of the research and post-graduate students mentioned in the question should normally be used, either in the Forces or in civil life, in such a way as to make the best use of their scientific or professional abilities.

Mr. EDE: Does that apply to other universities than Cambridge—Sir V. WARRENDER: Yes, Sir. It applies to all students studying these scientific subjects

Availability of Radium

Mr. Charles TAYLOR asked the Minister of Health whether supplies of radium were now available for patients who were in urgent need of this treatment.—Miss HORS-

BROOK replied I understand that in view of the great danger to the public which would exist if radium were dispersed by high explosive action, the Radium Commission and other holders have caused their radium to be deposited in places of safety and that it is not at present available for therapeutic purposes Provision for X ray therapy is being as far as possible maintained I am communicating with the commission with a view to their considering the possibility of making radium available for treatment subject to suitable safeguards

Evacuation Another Chance?

Miss WARD asked the Minister of Health whether he could arrange for a further opportunity in the near future to register for evacuation to be given to mothers with young children, expectant mothers, cripples and blind persons.—Mr ELLIOT replied In a circular letter of the 7th September I informed the local authorities that it was desirable that parents of school children resident in evacuating areas who did not take advantage of the Government scheme should be granted a further opportunity to register their children in the event of any further movement being found possible This further registration is limited to children of school age who would be evacuated without their parents, and it has now been carried out in most of the evacuation areas The further evacuation of members of the priority groups other than unaccompanied school children will have to receive careful consideration in the light of experience

Nursery Schools in Reception Areas

Mr THEW asked the Parliamentary Secretary to the Board of Education whether, in view of the large number of children under five years of age now likely to be permanently resident in reception areas, any steps had been taken to provide emergency courses for trained assistants in nursery schools.—Mr Kenneth LINDSAY replied The question of providing for children under five years of age in the reception areas is being actively considered by the departments concerned The needs of the present moment are, however, too urgent to wait for the establishment of nursery schools of the ordinary type, and must be met by more makeshift measures While arrangements for training helpers may have to be made such training would necessarily be different from that given in ordinary circumstances to trained assistants in nursery schools

Cheap Milk for Mothers and Children

Mrs ADAMSON asked the Minister of Health whether he was prepared to put into operation immediately the scheme for the provision of cheap milk for mothers and young children on the same basis as the milk in schools scheme, so as to ensure that the cheap milk would be available on application to any expectant and nursing mother and preschool child.—Mr ELLIOT replied The scheme for this purpose made by the Milk Marketing Board and approved by the Minister of Agriculture and Fisheries came into operation on July 31 I have received proposals under the scheme from a number of welfare authorities, and these are at present being examined by my department in consultation with the board, and I hope it will be possible to put them into operation at an early date

Nurses at First-aid Posts

Dr HADEN GUEST asked the Minister of Health, whether he was aware that experienced trained nurses and nursing sisters had been invited to volunteer for national service in London, and on appointment by borough councils had been paid £2 a week, the salary of first aid workers and whether a different scale of salaries could be established for trained nurses.—Mr ELLIOT replied The standard rate of £90 a year for a trained nurse plus board lodging and laundry, is applicable to a nurse employed by the borough council at a first-aid post under conditions laid down in a recent circular He would be glad he added, to look into any cases which were brought to his notice

Vaccination of Soldiers

Mr RHYS DAVIES asked the Secretary of State for War if he would make it clear to the responsible officers that vaccination of soldiers was not compulsory.—Sir V. WARRENDER (Financial Secretary to the War Office) replied A man is not enlisted into the Regular Army on a normal engagement unless he consents to be vaccinated Vaccination will not be compulsory in the case of other soldiers, and instructions have been issued to this effect

Night-baking

Mr BANFIELD asked the Home Secretary whether, in view of the severe hardship now being experienced by night bakers owing to the absence of ventilation due to the black-out, he would consider prohibiting night-baking between the hours of 6 P.M and 6 A.M.—Sir JOHN ANDERSON replied I have had special inquiries made from which it appears that while conditions as regards temperature and ventilation were in some cases adversely affected at first by black-out arrangements, they are now being improved On the information before me, I do not think that such new factors have arisen as would justify the prohibition of night baking at the present time

Extension of Summer-time

Sir JOHN ANDERSON (Home Secretary) announced that the Government proposed that summer time should this year be extended until the night of Nov 18–19

IN ENGLAND—NOW

(FROM OUR PERIPATETIC CORRESPONDENTS)

AT the end of three weeks of war, one of my chief impressions is of innumerable committees, medical board meetings, and interviews with house-physicians and surgeons and others who want answers to questions, which neither I, nor indeed the various officials who ought to know, seem able to give Incidentally, the capacity of officials to avoid giving a straight answer to a straight question, especially in writing, fills me with awe, in these weeks I have only come across one, a group officer and a surgeon, who if he obviously had not an answer to the question, said with refreshing frankness, "I don't know"

In Liverpool, with our target of docks (I suppose that by now the Germans have learned from their secret service that we are a seaport, and therefore I am not giving away secrets to the enemy), we most of us expected an early visit from the bombers By now, however, we have had time to assess a little more clearly some of the hospital problems involved in the transition from nominal peace to actual war "Extreme peril authorises many measures which should be rejected under other circumstances," said our old friend Celsus, and the provision of large numbers of empty beds for probable air-raid casualties was surely fully justified Had there already been heavy bombing of towns, a government which had failed to provide adequate numbers of beds for the casualties would have been severely criticised, and by none more than our own profession But all of us who have seen how the plan has affected our own hospital patients feel strongly that better provision must be made for them in any future evacuation Administrators may juggle with figures on paper, so that Parliament and people may be assured that a particular number of empty beds are now ready for casualties, but the practising doctor knows that his bed-ridden cases, transferred elsewhere because they are not fit to send home, still need skilled and adequate medical and nursing attention, bed pans and urine bottles It is of course just because practising doctors have a moral responsibility for the welfare of John Smith and Maggie Brown and Tommy Robinson that they are sensitive to the "faults in the machinery," and there is no doubt that goodwill and cooperation can put right difficulties which have arisen largely from the pressure of these initial days of war

It has been interesting to watch the functioning of medical boards of voluntary hospitals when con

fronted with the need for organising their own hospital duties in time of war. The members of my own medical board are pretty strong individualists, of diverse and specialised experience, and we were faced with the need for common thought and action to meet an urgent problem, and to fill in the practical details of an already prepared skeleton scheme. The give and take of discussion, and the sharing of initiative and responsibility, have produced a strong unity not only of general purpose but also of detailed organisation. I find it a mentally exciting experiment in true democratic method, and it works well. These meetings are far more satisfying in their results than were most of our medical board meetings in recent years of peace; the urgency of the times has intensified our sense of common purpose, we are less selfish and are willing to give more time to putting forward our own views, to listen to others, and to allow the common "sense of the meeting" to emerge. Perhaps it could not have happened had we not had leisure forced upon us by a great diminution of consulting and hospital practice since the war began, and our hospital beds were largely emptied; we are not distracted and hurried by the thought of all the work which is being interrupted by the meeting.

Whatever may be the social consequences of football pools, I imagine that Professor Davie will be relieved to hear that professional football and the pools are to go on; for large numbers of the girls employed in the offices of various pool firms are on the list of donors for the war blood bank. Certain offices vied with each other in providing volunteers, and scored remarkable figures These donors are not now likely to diffuse out of Liverpool.

By the way, the blood of Liverpool is sound. Out of some 5000 volunteers, men and women, whose blood was tested for blood bank purposes, only two were found to have a positive Wassermann reaction.

"I'll tell you what I'd do to Hitler," said a meek-looking man to another, in the tram going home; "I'd do what they did to Napoleon—send him to St. Helens."

* * *

I went on Monday to see my mother, a sprightly old lady of 85, who lives on the outskirts of a country town some twenty miles from London. She was revelling in the mild warm weather after the change from heat to cold of the previous week and, my sister being out, walked about the sitting-room changing all the cushions from one chair to another. We decided to have our chat in the garden, where again she refused to sit in the first four places in which I put her chair, and finally, revolting even against my choice of seat, sat herself upon the hard garden one. We had got through her aches and pains, the story of her last two tenants including why they left, and had reached A.R.P., when my sister came in with an elderly cousin The conversation at lunch turned to the subject of the Londoners billeted in the town, and I had to protest against the tacit assumption that the arrivals were a sort of inferior race. First I drew my mother's attention to the fact that the term for them was evacuees, not refugees, which we apply to those more unhappy persons who have escaped from persecution. The Londoners had not fled from the brutalities of the Metropolitan Police, but had been emptied out of their homes by these and other kindly officials. It was while we were discussing the disposal of the family dining-table that my sister spoke of "those Londoners" in a tone of superiority. It all arose out of the need of cutting down fuel expenditure. They will not be able to have a fire in both their rooms every day in the coming winter, and so the dining-room is to become their sitting-room, the drawing-room being for A.R.P. Now the old table at which, with two leaves and another one an inch higher added at the end, the family circle used to gather to the number of twenty or more on New Year's Eve is already too big for the room, and what were they to do when they had moved in a sofa for my mother to rest on with her feet up? The suggestion was that they should give it—lend, said I, not give—to the hostel that was being fitted up for the reception of expectant mothers. It was then that my sister said, "I don't quite like it going for the use of *those* Londoners." I drew myself up to my full height—we had finished lunch and I was standing in front of the fireplace drinking a cup of tea—and throwing back my shoulders said: "If the old family table is to go, no better purpose can it be put than for the use of London evacuees and their babies; surely" I added, "it is a very good idea, the hostel will be grateful to you for your generosity, and you will get it housed free, gratis, and for nothing for the duration of the war. It may of course get a bit stained." "Oh! that won't matter," granted my sister, "no one will want the old thing." "There, my dear, you're wrong," said I; "not you or I; but in 60 years' time Pip (that's my granddaughter now aged one) will be showing off that table as a lovely piece of mid-Victorian light oak. 'And,' she will say, 'do you know, that during the second German war they actually let it be used in a home for babies. There's the stain where the nurses used to throw down the nappies' And at that, if she is as like her grandmother as she promises to be, she will bend down and rub and polish trying to get out the stain that'll be one of the prides of her life." So I think the table will go.

The rest of the week I have spent in practising economy of petrol ready for tomorrow. I throw out my clutch at every little decline; I do not go down into second, at the corners, as often as I used, and hope this will not result in damage to the car At the lights I turn off my engine. When I am at the back of the block at a main cross-road this works well; but when I am at its head before quick-changing lights it results in disturbing hoots behind me when I do not get off at the yellow. It is remarkable how the driver's emotion can get into the hoot of his car But most valuable of all, I am learning to obey the law in the built-up areas, for I know that my car runs best at thirty miles per hour. The funny thing is, I am no later at my destinations. I have already had an aluminium plate fixed in front of one half of my radiator, for the doctor seldom runs far at once and always, therefore, with a cold extravagant car. Even if I get a special ration, with all my economy I foresee it is going to be hard to do my work. Walking will do me good, and I am looking to the soles of my boots. I am also thinking of a push-bike.

* * *

In Bristol we are fortunate. There has been almost no dislocation of our lives. Of course a good many government departments have descended upon us, but no evacuated schoolchildren or mothers and babies—for we are a neutral area The university is to receive the medical students from the Middlesex. Our medical staffs are almost intact, mainly because we have very few young men on our hospitals Our hospitals were emptied by order on the outbreak, but since no civilian casualties have occurred we are allowed to readmit ordinary cases again. The Conjoint is making Bristol one of its centres. I can't say how the additions to our university will affect us, but the work under new conditions hasn't begun yet. Meanwhile you must remember how very unexcitable Bristol is. I think our medical preparedness is much better than it was in 1914. Our local emergency medical committee works smoothly and well.

* * *

It is difficult to say how things will work out here in Cardiff. We expect a number of evacuee students. Along with this, the number of beds available at the Cardiff Royal Infirmary has been cut down to 200, and we are trying to arrange for the greater use of Llandough hospital, which has also been cut down to 175 beds and is rather far away from the centre of

niversity of Cambridge

Full arrangements have been made for the teaching of natomy and physiology in the coming term The regulation requiring a candidate for the final M.B., B Chir to ave obtained honours in a tripos or in a part or section of tripos, will be suspended There will therefore be a greater number of students ready to start clinical work in October than usual so the university contemplates giving three months course in pathology in conjunction with preliminary clinical work at Addenbrooke's Hospital . is hoped that a course for the examination in pharmacology will be given every term in conjunction with a course in pathology

niversity of Leeds

The Harveian festival, including the oration which was to be held on Oct 18, has been cancelled

General Medical Council

Prof J H Burn has been nominated by the King on the advice of the Privy Council to be a member of the General Medical Council in succession to Sir George Newman

Royal Society of Medicine

The society's house reopened on Sept 18 and will be open from 9 A.M to 5 P M including Saturdays until the evenings draw in, when the hour of closing will be earlier Meetings will be held in the mornings and early afternoons as notified on the diary card Proceedings will be published monthly, and the library services will continue as usual Fellows who are in the fighting services are invited to communicate their service titles and address to the secretary as soon as possible in order that adjustments may be made in subscription rates

working under the local authorities in Sanitary Inspectors' Association, in succession to the Sanitary Inspectors' War Service Committee, which was formed during the war to do today, as ready to carry on the work which the military organization The private members' work of the Association will be sent to the Headquarters, 108 North Street Glasgow.

EMERGENCY NOTICES

The dinner for old students of the Welsh National School of Medicine, Cardiff which was to have taken place in London on Oct 14 has been postponed indefinitely

The autumn meeting of the British Orthopædic Association which should have been held in Cardiff on Oct 27 and 28 has been cancelled

The St Mary's Hospital annual dinner, arranged to be held on Sept 30 has been cancelled.

The examinations for the membership and diplomas of the Royal College of Obstetricians and Gynæcologists will be held as previously arranged

The autumn exhibition of the medical art society will not be held

The work of the Universities' Federation for Animal Welfare is being continued from Gordon House, 29, Gordon Square London W.C 1

The Lancet 100 Years Ago

September 28, 1820, p 8

From an account of the London medical schools

Education *should* be free and unfettered It is coloured cribbed, confined, But though we demand its emancipation yet until its freedom is achieved, we must bend to the duties of the time, and render to the objects of a despotic and oppressive rule, expositions of its enactments, and of the mode of compliance therewith, in order that the penalties of infringement or neglect may be avoided . But incomparably more gratifying would be the duty of opening to his view, the pure, broad, sparkling streams which must flow from the natural fountains of knowledge, than that of mapping down the artificial conduits and turbid tanks of the usurping dispensers of the waters of science) At present medical education is bound as to periods, places, and pursuits Pinned to the earth, like the prostrate Gulliver, by the hair, the arms, the feet it has neither life nor motion nor power to look around Escaped from the enemies who made it captive in the days when education was asleep free as its legs—at will—an intellectual giant, I mustered from the pygmy foes,—assume a noble part

Notes, Comments and Abstracts

A COMMUNITY OF CHILDREN

THE Caldecott Community has for many years been providing refuge and education for "normal children from abnormal homes" As the world becomes more and more abnormal the scope of such work must change and widen, and we learn that fifteen refugee children have already been admitted to the community, and that evacuated children who were unhappy or difficult in their billets have also been received. A scheme of preliminary investigation and examination of children before their admission has now been introduced, and the examination is made at the Tavistock Clinic

The community has no endowment and is in urgent need of money. Though calls for help are now innumerable, there will be some of our readers who feel that the sound care and happiness of children is one of the objects they most wish to promote. Those interested can get further particulars from the hon directors, The Mote, Maidstone, Kent.

ROTES KREUZ AND HACKENKREUZ

IN a disarming article in the *Wiener Klinische Wochenschrift* (1939, 52, 258) Dr. Walter Ott, Generalfuhrer of the German Red Cross, soothes any scruples the conscientious Nazi may have about the orthodoxy of the principles on which his organisation is founded. He admits that some years after its foundation—in the times of liberalism when so much sentimental nonsense was talked in the name of humanitarianism—the red cross may have assimilated a slightly pacifist flavour. But he points out the original idea of the movement was born on the battlefield and developed during the various wars of the past and especially during the world war Any doubts that may have arisen in the minds of his readers are simply due to looking at the subject from the wrong standpoint. If they think back to their own experiences in the Great War they will remember that after the hatred of battle has died away the soldier regards his wounded enemy with different feelings. He recognises him as one who, like himself, is but fighting for his native land; he sees him no longer as an enemy but as a man honourably wounded in battle, with whom he is ready to share his last cigarette and drink of water Regarded in this (?) less sentimental light Dr. Ott is confident that the Nazi will recognise the red cross as the expression of a heroic chivalry.

GOLDEN LOTUS

THE bound feet of Chinese women are discussed in all their aspects—historical, anatomical, physiological, pathological, geographical, and psychological—by A. Bigot, who concludes that they constitute an artificially produced variety of the otherwise congenital deformity known as club-foot or talipes equinus (*Rev. méd. franç. Ext.-Orient*, April, 1939, p. 321). This production of club-foot by intentional compression, begun at a tender age, tallies with Denis Browne's theory of intra-uterine compression of the fœtus as the cause of congenital talipes (*Lancet*, 1934, 2, 969); indeed he refers to the "relevant experiments on the female human foot" made by the Chinese (*Brit. med. J.* 1937, 2, 570) Bigot shows that compression dislocates the head of the astragalus, a dislocation adduced as the cause of congenital club-foot by E P. Brockman, who asserts that it is not due to external compression but to "an atresia of the socket into which the head of the astragalus normally fits" (*Ibid.* p. 572). This custom of *kin-lien*, meaning "golden lotus," is confined to China, where it has flourished fifteen hundred years owing to the deeply rooted foot-fetichism of the inhabitants, to the exclusion of the many other mutilations to which women throughout the world submit in the cause of mistaken beauty.

Vacancies

Burnley County Borough —Asst M.O , £850. Also sen M.O H , £800
Cambridge, Addenbrooke's Hosp.—H P , at rate of £130.
Chelmsford Borough —M O H and school M O , £800
